## **Foreword**

This document specifies the MODBUS parameters of the device "product range" from ebm-papst.

This excerpt differs from the full document in that it does not describe parameters for ebm-papst internal use. These parameters are marked with the word "Reserved".

Knowledge of the general MODBUS specifications is assumed:

- MODBUS over Serial Line Specification & Implementation guide V1.0
- MODBUS Application Protocol Specification V1.1

The documents are available in the internet at modbus.org

The general MODBUS specifications form the basis for this document and apply in full with the exception of the restrictions described in this document.

# **Change history**

Version	Changes
1.00	Document creation
1.01	
1.02	
2.00	Change to coding of the following registers from 8-bit to 16-bit (previously MSB was always 0):
	a) Holding registers
	D001 Default set value
	D114 / D115 Set value (EEPROM)
	D12A - D12D Potentiometer characteristic curve
	b) Input register
	D010 Actual speed
	D01A Current set value
	D01B Sensor actual value
	Change to coding of control parameter I factor (resolution 11/65536 instead of 2561/256) Change to controller equation (kp no longer influences I component)
	Definition for ramp-up curve / ramp-down curve changed, as set value can now assume 65536 steps instead of 256 steps
	Default set value no longer stored in "Set value (stored)" parameter with write access but rather in "Set value (EEPROM)"; "Set value (stored)" parameter no longer used
	Identification 0x0002 re-defined for Modbus Parameter Specification V2.00
2.01	Addition of the following holding registers:
	D135 Max. power
	D136 - D138 Parameters for derating max. power
	D13B Max. coil current
	D13C - D13F Potentiometer characteristic curve "Night"
	D140 - D143 Characteristic curve output 010 V
	Re-definition of holding register D12F: "Limitation Control"
	The falls of the Line we detect and the state of
	The following holding register has been deleted:
	D11D Max. DC-link current
	Addition of input register D021 Current power
	Addition of new bits in input register D012 Warning: P_Limit and I_Limit
	Addition of now bits in input register borz warning. F_Limit and i_Limit
2.02	
3.00	Addition of the following holding registers:
3.00	D009 Operating hours counter
	D00A Operating minutes counter
	D145 Run monitoring speed limit
	D15C Bypass function on / off
	D15D Bypass function set value
	D15E Bypass function time delay
	15.62 Sypaco ranouon amo dolay

Version	Changes					
	Function of following holding registers changed					
	D180 Operating hours counter: now only back-up					
	D181 Operating minutes counter: now only back-up					
	Addition of new bits in input register D012 Warning: n_Low					
3.01						
3.02	Addition of the following holding registers:					
	D148 Switch for rotating direction source					
	D147 Sensor actual value source					
	Change to the following holding registers:					
	D104 Switch for parameter set source (new value: 2)					
	D12E Switch for for controller function source (new value: 2)					
	D130 Function output 010 V (new value: 2)					
	D184ff Error history: Bit 15 "Brake" deleted					
	Bit 14 "UeHigh" added					
	D1A2 -D1A3 Fan serial number					
	D1A4 Date of fan manufacture					
	Addition of the following input registers:					
	D023 Sensor actual value 1					
	D024 Sensor actual value 2					
	Change to the following input registers:					
	D011 Motor status: Bit 15 "Brake" deleted					
	Bit 14 "UeHigh" added Bit 13 "UeLow" added					
	D012 Warning: Bit 7 "Brake" added					
	Warning. Dit / Drake added					
	Renaming of the following holding registers:					
	D102 Preferred running direction (instead of running direction)					
	D104 Switch for parameter set source					
	(instead of day / night switching external / internal)					
	D105 Parameter set internal (instead of day / night internal)					
	D12E Switch for controller function source (instead of controller function switch					
	between external / internal)					
	D15C Fail-safe function on / off (instead of bypass function on / off)					
	D15D Fail-safe set value (instead of bypass function set value)					
	D15E Time lag fail-safe speed (instead of emergency operation function time lag)					
	All "Day" designations renamed "Parameter set 1"					
	All "Night" designations renamed "Parameter set 2"					
	Panaming of the following input register:					
	Renaming of the following input register:					
	D01D Current parameter set (instead of parameter set day / night)					
4.00	New command:					
	0x46 Write single register addressed by serial no.					
	Permit change of interface setting					
	Fail-safe function extended to analog input (cable break detection)					
	Addition of the following holding registers:					
	D149 Transmission speed					
	D14A Parity configuration					
	D15F Potentiometer characteristic, limit value for cable break curve					

Version	Changes				
	Addition of the following input register				
	D012 Warning: Bits 10 "Cable break", 1 "L_high" added				
	Write authorization changed for holding register				
	D145 Run monitoring speed limit (customer)				
5.00	New commands:				
	0x43 Read holding register addressed by serial no.				
	0x44 Read input register addressed by serial no.				
	0x50 Write multiple register addressed by serial no.				
	Broadcast addressing for all commands " Addressed by serial no."				
	Maximum telegram length increased to 23 bytes				
	Change to the following holding registers:				
	D130 Function 010 V output / speed monitoring: new value 3 (actual speed				
	-> pulses per revolution); MSB: pulses per revolution added				
	D149 Transmission speed (new values: 6, 7 -> 57600, 115200 bits/sec) D182 - D19F Error history: Bits 14 "UeHigh", 11 "UzHigh" and 9 "TFEI" deleted				
	Dioz Dioi Enormatory. Dita 14 Oct light, 11 Ozi light and 3 11 En acicted				
	Addition of the following holding registers:				
	D14D Motor temperature power derating start				
	D14E Motor temperature power derating end				
	D150 Shake-loose function				
	D151 Max. starting modulation level				
	D152 Max. number of start attempts				
	D153 Relay drop-out delay D155 Max. power				
	D15B Rotating direction fail-safe mode				
	2 102 Trotaining amounts name and mount				
	Renaming of the following holding registers:				
	D135 Max. permissible power				
	D136 Max. power at temperature derating end				
	D137 Module temperature power derating start				
	D138 Module temperature power derating end				
	Change to the following input registers:				
	D011 Motor status: Bits 14 "UeHigh", 13 "UeLow, 11 "UzHigh" and 9 "TFEI" deleted				
	D012 Warning: Bits 15 "LRF", 14 "UeHigh", 12 "UzHigh" and 11 "Heating" added				
	D016 Motor temperature (format: signed integer; permit negative values)				
	Renamed all occurrences of emergency operation to fail safe function and a few failure and				
5.02	warning bit texts for consistency with EC-Control.				
6.00	Maximum telegram length increased to 80 bytes				
	Addition of the following holding registers:				
	D00C Addressing on / off				
	D00D - D00E Stored set value				
	D00F Enable / Disable RS485				
	D010 Remote control output 0-10 V				
	D158 Configuration I/O 1				

Version	Changes
	D159 Configuration I/O 2
	D15A Configuration I/O 3
	D16A Switch for Enable / Disable source
	D16B Stored Enable / Disable RS485
	D16C Switch for set value source
	D16D Power derating ramp
	D16E Voltage output
	D16F RFID access
	D1F7 Rotor position sensor calibration set value
	D1F8 Rotor position sensor calibration
	D380 - D39F Mirrored holding registers
	D400 - D40F Original addresses of mirrored input registers
	D480 - D49F Original addresses of mirrored holding registers
	2 100 2 101 Original additional of minorod molaring regional
	Renaming of the following holding registers
	D12A - D12D Potentiometer characteristic curve (par. 1) -> Input characteristic curve (par. 1)
	D13C - D13F Potentiometer characteristic curve (par. 2) -> Input characteristic curve (par. 2)
	D15C Emergency operation function on / off -> Emergency operation set value source
	D15F Open circuit limit value potentiometer characteristic curve->Open circuit limit
	value input characteristic curve
	Change to the following holding registers:
	D101 Set value source: Values 2 and 3 extended: Ain2, PWMin3
	D104 Switch for parameter set source: Value 3 extended: Din1
	D12E Switch for controller function source: Value 3 extended: Din1
	D130 Function output 0-10 V: Values 4 + 5 extended (addressing, remote control)
	Value 3 deleted (actual speed pulses per revolution)
	D148 Switch for rotating direction source: Value 3 extended: Din1
	D15C Fail-safe set value source (values 2 - 4 extended: Ain1, Ain2, PWMin3)
	D182 - D19F Error history: Bit 8 (n_Limit) added
	Broz Broz Error motory. Bit o (in_Emm) added
	Addition of the following input registers:
	D027 Current power [W]
	D028 Current set value source
	D029 - D02A Energy consumption counter
	D100 - D10F Mirrored input registers
	Change to the following input registers:
	D011 Motor status: Bits 10 + 8 (RL_Cal, n_Limit) added
	D012 Warning: Bit 8 RL_Cal added
	Renaming of the following input register:
	D01C Enable input state -> Enable / Disable input state
	Access option via RFID interface
	June 19th: replaced two drawings which still contained German contents

## **Protocol frame**

Data transmission using the MODBUS protocol defined in this specification takes place solely in an environment defined as Master - Slave system. The ordered flow of data is governed by the master. A slave has to respond to a command request from the master. When structuring a system, it is therefore important to ensure that a slave address is not allocated twice.

The preferred transmission medium is a twisted-pair cable with RS485 standard.

RTU is the only transmission mode supported (see MODBUS over Serial Line Specification & Implementation guide V1.0, Section 2.5.1)

ASCII transmission mode is not supported!

## Byte structure

In accordance with the MODBUS over Serial Line Specification & Implementation guide V1.0, a byte has the following structure:

The definition of the parity bit ("Even", "Odd", "None") can be set by way of the parameter "Parity configuration" (see 2.42.2).

The transmission speed is variable and can be set by way of the parameter "Transmission speed" (see 2.42.1).

#### **Communication process**

MODBUS over Serial Line Specification & Implementation guide V1.0 defines the following frame for the transmission protocol:

Command from master:	Start > 3.5 char	Address 8 bits	Command 8 bits	Data N * 8 bits	CRC L 8 bits	CRC H 8 bits	
Response from fan:	Start > 3.5 char	Address 8 bits	Command 8 bits	Data N * 8 bits	CRC L 8 bits	CRC H 8 bits	

Contrary to the general specification the maximum telegram length is 80 bytes.

#### 1.2.1 Command from master

A master device is a PC or a control unit, for example.

#### Start synchronization:

Start synchronization is provided by a silent interval of at least 3.5 bytes. The next following byte is then interpreted as the first byte of a frame (i.e. address). The interval between the individual bytes of a frame must not exceed 1.5 bytes.

#### Address:

The size of the address field is 8 bits.

Address values between 1 and 247 are permitted

The address 0 is intended for broadcast commands (i.e. command to all fans in the network).

#### Command:

The following commands of the general specification "MODBUS Application Protocol Specification V1.1" are supported:

Code	Command
0x03	Read holding register
0x04	Read input register
0x06	Write single register
0x08	Diagnostics
0x10	Write multiple register

The other commands are not supported.

ebm-papst has additionally defined the following commands:

Code	Command
0x43	Read holding register addressed by serial no.
0x44	Read input register addressed by serial no.
0x46	Write single register addressed by serial no.
0x50	Write multiple register addressed by serial no.

#### Data:

The number of data bytes and their meaning differ depending on the command. See 1.3 Commands

#### CRC L / CRC H

A checksum CRC is formed across the entire telegram.

The polynomial for checksum formation is  $1 + x^2 + x^{15} + x^{16}$  (i.e. XOR operation with 0xA001).

The start value is 0xFFFF.

The low byte of the checksum is transmitted first, then the high byte.

Further information on calculating the checksum can be found in the "MODBUS over Serial Line Specification & Implementation guide V1.0".

#### 1.2.2 Response from fan

A fan only responds if

- It has been addressed with its own address.
   No response is transmitted in the case of a broadcast address.
- The telegram length is max. 80 bytes.
- The correct number of data bytes has been transmitted to permit interpretation of the telegram.
- The checksum has been correctly detected.

#### Start synchronization:

Following completion of the command from the master the fan waits for a silent interval of *at least* 3.5 bytes to elapse. Depending on the command and processing time, the interval may also be considerably longer (until all the requested data are available to the fan)

For access times to holding registers, see 2.1

#### Address:

The address from the command of the master (i.e. the fan's own address) is repeated

#### Command:

If the command can be processed, the command code is repeated.

If the command cannot be processed, the fan responds with an exception.

In this case, the MSB is set in the command.

The command byte for the command "Read holding register (0x03)" is then 0x83 for example.

## Data:

The number of data bytes and their meaning differ depending on the command. See 1.3 Commands.

#### CRC L / CRC H

A checksum CRC is formed across the entire telegram.

The checksum formation process is the same as the procedure described above for the command from the master.

#### 1.3 Commands

### 1.3.1 Read holding register

Command code: 0x03

The content of several holding registers can be read out with this command. Holding registers are parameters for which both read access and write access exist

#### Command from master:

4 data bytes are transmitted:

- 1st holding register address MSB
- 1st holding register address LSB
- Number of addresses to be read MSB
- Number of addresses to be read LSB

The holding registers will be described later.

#### Response from fan:

The following data bytes are transmitted:

- Byte count (number of addresses to be read \* 2)
- Data of 1st holding register MSB
- Data of 1st holding register LSB

#### Optional:

• Data of the following holding registers (0..n)

#### Exception codes:

Just one data byte (exception code) is transmitted in the event of an error

#### Exception codes:

0x02: The permissible range of the holding registers 0xD000 ... 0xD5FF has been exceeded

(03: The maximum telegram length for the response (80 bytes) has been exceeded,

i.e. more than 37 holding registers or 0 holding registers were requested.

0x04: A holding register cannot be read on account of a fault in the electronics

#### 1.3.2 Read input register

Command code: 0x04

The content of several input registers can be read out with this command. Input registers are parameters for which only read access exists.

#### Command from master:

4 data bytes are transmitted:

- 1st input register address MSB
- 1st input register address LSB
- Number of addresses to be read MSB
- Number of addresses to be read LSB

The input registers will be described later.

#### Response from fan:

The following data bytes are transmitted:

- Byte count (number of addresses to be read \* 2)
- Data of 1st holding register MSB
- Data of 1st holding register LSB

Data of the following input registers (0..n)

#### **Exception codes:**

Just one data byte (exception code) is transmitted in the event of an error

#### **Exception codes:**

The permissible range of the input registers 0xD000 ... 0xD2FE has been exceeded 0x02: The maximum telegram length for the response (80 bytes) has been exceeded, 0x03:

i.e. more than 37 input registers or 0 input registers were requested.

#### 1.3.3 Write single register

Command code: 0x06

The content of one holding register can be written with this command.

#### Command from master:

4 data bytes are transmitted:

- Holding register address MSB
- Holding register address LSB
- Data to be written MSB
- Data to be written LSB

The holding registers will be described later.

#### Response from fan:

4 data bytes are transmitted:

- Holding register address MSB
- Holding register address LSB
- Data to be written MSB
- Data to be written LSB

#### **Exception codes:**

Just one data byte (exception code) is transmitted in the event of an error

#### Exception codes:

The permissible range of the holding registers 0xD000 ... 0xD5FF has been exceeded

- The holding register cannot be written on account of a fault in the electronics

- There is no write authorization at this authorization level (password).

#### 1.3.4 Diagnostics

Command code: 0x08

The Modbus function can be checked with this command.

#### Command from master:

The following data bytes are transmitted:

- Subfunction code MSB
- Subfunction code LSB
- 1 17 data bytes

Only the subfunction code 0000 is supported.

#### Response from fan:

The following data bytes are transmitted:

- Subfunction code MSB
- Subfunction code LSB
- 1 17 data bytes

#### **Exception codes:**

Just one data byte (exception code) is transmitted in the event of an error

#### Exception codes:

0x01: Subfunction code is not supported (≠ 0000)

#### 1.3.5 Write multiple register

Command code: 0x10

The content of several holding registers can be written with this command.

#### Command from master:

The following data bytes are transmitted:

- Holding register address MSB
- Holding register address LSB
- Number of addresses to be written MSB
- Number of addresses to be written LSB
- Byte count (number of addresses to be written \* 2)
- Data to be written 1st holding register MSB
- Data to be written 1st holding register LSB

#### Optional:

Data to be written of the following holding registers (0..n)

The holding registers will be described later.

#### Response from fan:

4 data bytes are transmitted:

- Holding register address MSB
- Holding register address LSB
- Number of addresses to be written MSB
- Number of addresses to be written LSB

#### **Exception codes:**

Just one data byte (exception code) is transmitted in the event of an error

#### Exception codes:

0x02: The permissible range of the holding registers 0xD000 ... 0xD5FF has been exceeded

0x03: - The maximum possible number of registers has been exceeded,

i.e. more than 123 holding register data or 0 holding register data were defined

- Byte count ≠ 2 \* number of registers
- Number of data bytes ≠ byte count

0x04: - The holding register cannot be written on account of a fault in the electronics

- There is no write authorization at this authorization level (password).

#### 1.3.6 Commands with addressing by serial number

These commands additionally use the serial numbers of the fans for addressing:

An identifier for the serial number of the fan (6 bytes) is transmitted in the data area of the commands. Only the fan with the MODBUS address and serial number specified in the command reacts to the command and responds.

The command with addressing by serial number is obtained from the standard command by inserting an identifier for the serial number after the command byte.

#### Serial number format:

ebm-papst allocates an individual serial number for each fan. The part which customers can read out is made up of the date of manufacture and the consecutive number. Addressing is also possible with this. Should any unexpected problems arise, please inform us accordingly.

Format: YYWW00XXXX

ΥY : Year of manufacture WW : Week of manufacture 00 : Fixed value 00 XXXX : Consecutive number

The first 4 characters contain the date of manufacture (year / week).

The number XXXX starts running at zero at the start of each week of manufacture and is incremented by 1 for each fan. Each character can assume values from 0-9 and from A-Z. This yields a maximum encodable number of 36 characters per position, i.e. 36 <sup>4</sup> = 1 679 616 devices / week

#### Example:

ebm-papst serial number: 09230012GY Year of manufacture: 09 (2009)Week of manufacture: 23 (23)Consecutive no.: 12GY (49525)

The year and week of manufacture are each coded as a hex value in the command.

Each character of the consecutive no. is coded as an ASCII value.

In commands with addressing by serial number the serial number must be specified as follows:

Byte no.	Meaning	Example	Corresponds to holding register
Byte 0:	[Address]		
Byte 1:	[Command code]		
Byte 2:	Year of manufacture	0x09 (-> 2009)	D1A4 MSB
Byte 3:	Week of manufacture	0x17 (-> 23)	D1A4 LSB
Byte 4:	Consecutive no. 1st character	0x31 (-> 1)	D1A3 MSB
Byte 5:	Consecutive no. 2nd character	0x32 (-> 2)	D1A3 LSB
Byte 6:	Consecutive no. 3rd character	0x47 (-> G)	D1A2 MSB
Byte 7:	Consecutive no. 4th character	0x59 (-> Y)	D1A2 LSB

This sequence differs from the one in which the serial number is stored in the holding registers D1A2 - D1A4 (c.f. 2.61.1)!

#### Broadcast addressing

If the value 0x00 is transmitted in one or more bytes of the serial number identifier, the corresponding part of the serial number will not be checked by the fan. All the fans which have the rest of the serial number identifier will then respond.

All fans respond if all bytes are transmitted with the value 0x00.

In the response, the own address and serial number are given instead of the broadcast address / serial number 0x00.

#### Ways of determining the serial number:

- Printed on the nameplate of the fan
- Read serial number out of holding registers D1A2 D1A4 (c.f. 2.61.1)
- Broadcast addressing: The fan responds with its serial number

#### 1.3.6.1 Read holding register addressed by serial no.

Command code: 0x43

The content of several holding registers can be read out with this command. Holding registers are parameters for which both read access and write access exist.

Contrary to "MODBUS over Serial Line Specification & Implementation guide V1.0", the fan also responds to a broadcast command (Modbus address = 0).

#### Command from master:

10 data bytes are transmitted:

- Serial no. byte 1
- Serial no. byte 2
- Serial no. byte 3
- Serial no. byte 4
- Serial no. byte 5
- Serial no. byte 6
- 1st holding register address MSB
- 1st holding register address LSB
- Number of addresses to be read MSB
- Number of addresses to be read LSB

The holding registers will be described later.

#### Response from fan:

The following data bytes are transmitted:

- Serial no. byte 1
- Serial no. byte 2
- Serial no. byte 3
- Serial no. byte 4
- Serial no. byte 5
- Serial no. byte 6
- Byte count (number of addresses to be read \* 2)
- Data of 1st holding register MSB
- Data of 1st holding register LSB

#### Optional:

Data of the following holding registers (0..n)

#### Exception codes:

Just one data byte (exception code) is transmitted in the event of an error

#### Exception codes:

0x02: The permissible range of the holding registers 0xD000 ... 0xD49F has been exceeded

The maximum telegram length for the response (80 bytes) has been exceeded, 0x03:

i.e. more than 34 holding registers or 0 holding registers were requested.

0x04: A holding register cannot be read on account of a fault in the electronics

#### 1.3.6.2 Read input register addressed by serial no.

Command code: 0x44

The content of several input registers can be read out with this command. Input registers are parameters for which only read access exists.

Contrary to "MODBUS over Serial Line Specification & Implementation guide V1.0", the fan also responds to a broadcast command (Modbus address = 0).

#### Command from master:

10 data bytes are transmitted:

- Serial no. byte 1
- Serial no. byte 2
- Serial no. byte 3
- Serial no. byte 4
- Serial no. byte 5
- Serial no. byte 6
- 1st input register address MSB
- 1st input register address LSB
- Number of addresses to be read MSB
- Number of addresses to be read LSB

The input registers will be described later.

#### Response from fan:

The following data bytes are transmitted:

- Serial no. byte 1
- Serial no. byte 2
- Serial no. byte 3
- Serial no. byte 4
- Serial no. byte 5
- Serial no. byte 6
- Byte count (number of addresses to be read \* 2)
- Data of 1st holding register MSB
- Data of 1st holding register LSB

#### Optional:

Data of the following input registers (0..n)

#### **Exception codes:**

Just one data byte (exception code) is transmitted in the event of an error

## **Exception codes:**

The permissible range of the input registers 0xD000 ... 0xD10F has been exceeded 0x02: The maximum telegram length for the response (80 bytes) has been exceeded, 0x03:

i.e. more than 34 input registers or 0 input registers were requested.

#### 1.3.6.3 Write single register addressed by serial no.

Command code: 0x46

The content of *one* holding register can be written with this command.

Contrary to "MODBUS over Serial Line Specification & Implementation guide V1.0", the fan also responds to a broadcast command (Modbus address = 0) provided that no broadcast identifier (0) was used in the serial number. As two different fans cannot have the same serial number, it is impossible for several fans to respond to one command.

#### Command from master:

10 data bytes are transmitted:

- Serial no. byte 1
- Serial no. byte 2
- Serial no. byte 3
- Serial no. byte 4
- Serial no. byte 5
- Serial no. byte 6
- Holding register address MSB
- Holding register address LSB
- Data to be written MSB
- Data to be written LSB

The holding registers will be described later.

#### Response from fan:

10 data bytes are transmitted:

- Serial no. byte 1
- Serial no. byte 2
- Serial no. byte 3
- Serial no. byte 4
- Serial no. byte 5 Serial no. byte 6
- Holding register address MSB
- Holding register address LSB
- Data to be written MSB
- Data to be written LSB

The command from the master is repeated in the response

#### **Exception codes:**

Just one data byte (exception code) is transmitted in the event of an error

#### Exception codes:

The permissible range of the holding registers 0xD000 ... 0xD49F has been exceeded

There is no write authorization at this authorization level (password).

#### 1.3.6.4 Write multiple register addressed by serial no.

Command code: 0x50

The content of several holding registers can be written with this command.

#### Command from master:

The following data bytes are transmitted:

- Serial no. byte 1
- Serial no. byte 2
- Serial no. byte 3
- Serial no. byte 4
- Serial no. byte 5
- Serial no. byte 6
- Holding register address MSB
- Holding register address LSB
- Number of addresses to be written MSB
- Number of addresses to be written LSB
- Byte count (number of addresses to be written \* 2)
- Data to be written 1st holding register MSB
- Data to be written 1st holding register LSB

#### Optional:

Data to be written of the following holding registers (0..n)

The holding registers will be described later.

#### Response from fan:

10 data bytes are transmitted:

- Serial no. byte 1
- Serial no. byte 2
- Serial no. byte 3
- Serial no. byte 4
- Serial no. byte 5
- Serial no. byte 6
- Holding register address MSB
- Holding register address LSB
- Number of addresses to be written MSB
- Number of addresses to be written LSB

#### Exception codes:

Just one data byte (exception code) is transmitted in the event of an error

#### Exception codes:

The permissible range of the holding registers 0xD000 ... 0xD49F has been exceeded 0x02:

0x03: - The maximum possible number of registers has been exceeded,

i.e. more than 123 holding register data or 0 holding register data were defined

- Byte count ≠ 2 \* number of registers
- Number of data bytes ≠ byte count

0x04: - The holding register cannot be written on account of a fault in the electronics

- There is no write authorization at this authorization level (password).

#### 1.3.6.5 Applications

#### Initialization of an installation

All ex works fans have the same address 1. To be able to address each fan individually in the case of an installation made up of several fans, this address has to be changed so that each fan has a different address.

Standard procedure (command 0x06 Write single register):

- 1. Switch on the first fan (leave all others switched off)
- 2. Change the address using the command 0x06 Write single register
- 3. Switch on the next fan
- 4. Repeat steps 2 and 3 until all fans have an individual address

Procedure if serial numbers are known (e.g. printed on nameplate)

- 1. Switch on all fans
- 2. Change the addresses using the command 0x46 Write single register addressed by serial no.

Procedure if serial numbers are not known:

- 1. Switch on all fans
- 2. Identify the serial numbers using the command 0x43 Read holding register addressed by serial no. or 0x44 Read input register addressed by serial no. in Broadcast addressing with collision detection
- 3. Once a serial number has been identified:
  Change the Modbus address using the command 0x46 Write single register addressed by serial no.

The advantage over the standard procedure is that all the fans can be switched on simultaneously on initializing an installation. Each fan can be addressed individually despite having the same address 1. The master device (e.g. PC) can allocate an individual address to each fan without the need for any switching operations in the installation.

Implementation in master device (e.g. PC):

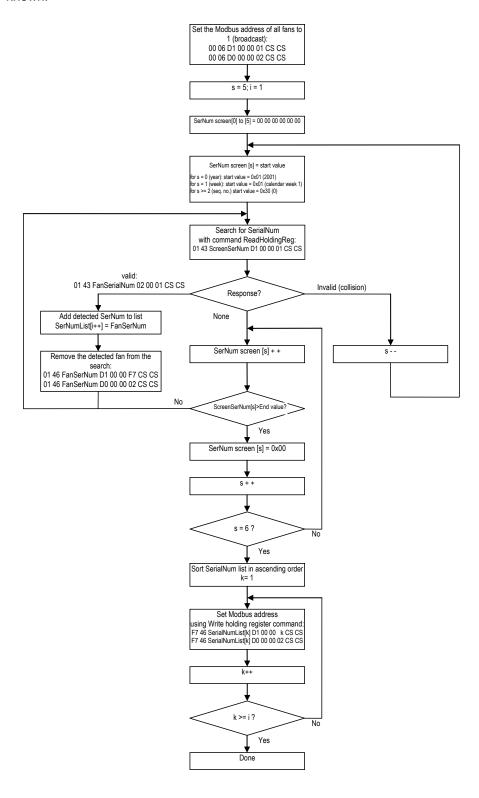

The following procedure is recommended for implementation in a master device if serial numbers are known:

- 1. The master device is informed of all serial numbers by way of manual input
- 2. A Modbus address is allocated to each fan by way of the serial number.

For this, 2 broadcast commands are required for each fan:

- a. Set holding register fan address (D100):
   00 46 SNo SNo SNo SNo SNo D1 00 00 Add CS CS (CS = CRC checksum)
- b. Set holding register reset (D000) to 0x02 Transfer parameter:
   00 46 SNo SNo SNo SNo SNo D0 00 00 CS CS
   SNo = fan serial number established: Add = allocated Modbus address

The following algorithm is recommended for implementation in a master device if serial numbers are not known:

#### Procedure:

On setting up the installation, the fans must be arranged in the ascending order of their serial numbers. This is necessary to ensure simple assignment of the automatically allocated Modbus addresses to the fans in the installation.

To start with, all fans are set to the MODBUS address 0x01.

2 broadcast commands are required for this:

- Set holding register fan address (D100) to 0x01: 00 06 D1 00 00 01 CS CS (CS = CRC checksum)
- Set holding register reset (D000) to 0x02 Transfer parameter: 00 06 D0 00 00 02 CS CS

All the serial numbers of the installation are determined in a loop:

The mask for serial number addressing is first set to Broadcast addressing

(00 00 00 00 00 00). The last byte is set to the start value 0x30 (0).

The mask SerNo is thus 00 00 00 00 00 30.

This mask is used to search for fans with the value 0x30 (0) at the last position of the serial number. Use can be made of any command for reading a holding register or input register, e.g. Read holding register fan address: 01 43 00 00 00 00 00 30 D1 00 00 01 CS CS

There are several possible outcomes for the response:

An unequivocal response:

The fan responds with its serial number (SerNoFan) in the address field.

This serial number is stored in a list.

The fan is then blocked for further requests by setting the MODBUS address to 0xF7 (247).

The same serial number then has to be polled again, as there is a possibility that a further fan may also have been addressed but did not respond as it had already detected the start of the response of the other fan on account of differences in runtime.

- An invalid response due to overlaid responses from several fans:
  - The serial number mask then has to be further restricted by also setting the next-to-last byte to the start value 0x30 (0). Only fans with the value 0x30 (0) at the last two positions of the serial number will then respond to the next request.
- No response:
  - All serial numbers with the value 0x30 at the last position can then be excluded. The last byte of the mask is incremented to the value 0x31 (1). All fans with the value 0x31 (1) at the last position of the serial number will then respond on next polling.

The loop is continued until all serial numbers have been polled:

- In the event of a valid response, the serial number of the fan is stored in the list
- In the event of an invalid response, the serial number range is further restricted by masking another byte, beginning with the start value. For the last 4 bytes the start value is 0x30 (0). The first two bytes have a start value of 0x01, as the year (2001) and week (W1) are coded here.
- If there is no response, the position concerned is incremented by 1 until the end value is reached. For the last 4 bytes the end value is 0x5A (Z). For the first byte (year), the end value is 0x63 (2099); for the second byte (W), the end value is 0x35 (W53).
  - Once the end value has been reached, the position concerned is addressed again by way of broadcast addressing (0x00) and the next position is incremented by 1. When the addressing for the last byte reaches the end value 0x5A (Z), all serial numbers have been checked. The polling of serial numbers can thus be concluded.

All the serial numbers found are then sorted in ascending order in the master.

A MODBUS address is allocated to each fan by way of the serial number.

For this, 2 commands are required for each fan:

- Set holding register fan address (D100): F7 46 SNo SNo SNo SNo SNo SNo D1 00 00 Add CS CS
- Set holding register reset (D000) to 0x02 Transfer parameter:
   F7 46 SNo SNo SNo SNo SNo D0 00 00 02 CS CS

SNo = fan serial number established; Add = allocated MODBUS address

#### Extension of address space

A maximum of 247 fans can be addressed with standard MODBUS commands.

The commands with addressing by serial number make it possible to address any number of ebm-papst fans with MODBUS interface. In this case the fan address is not made up of just one byte but rather of 7 bytes (MODBUS address + 6-byte serial number). This address is set at the factory and cannot be changed.

The serial number must be known to the master device (e.g. PC) for addressing, as a scan of all serial numbers is not possible on account of the large number involved. See above for determination of serial number (Initialization of installation).

With an extended address space, use can only be made of commands with addressing by serial number. Collisions are inevitable if standard commands are used, as several fans have the same MODBUS address.

#### Determination of unknown MODBUS address

- There must not be more than one fan connected to the bus
- Command 0x43 Read holding register addressed by serial no. or 0x44 Read input register addressed by serial no. in Broadcast addressing:
  - MODBUS address and serial number identifier are given as 0x00
- The connected fan responds with its MODBUS address and serial number

#### 1.3.7 Other commands

All other commands are not supported.

The response to a command is always the exception code 0x01.

# 2 Holding registers

#### 2.1 Overview

The holding registers are stored in the RAM and in the EEPROM of the fan. The access times (and thus also the response times) differ depending on the area

The following areas are defined:

Address	Area	Typ. time for read access	Typ. time for write access
D000 D0FF	RAM	1 μs / holding register	1 µs / holding register
D100 D37F	EEPROM	160 µs / holding register	6.3 ms / holding register
D400 D5FF			
D380 D3FF	Mirror range	See corresponding	See corresponding
	_	original range	original range

The following list provides an overview of all parameters.

In addition to the MODBUS address and the designation, it shows the authorization level required to write a parameter, as well as the address of the memory location for factory setting and customer setting (if applicable).

The function of the parameters is described in the following sections

MODBUS address	Designation	Write ebm-papst	Write Customer	Write End customer	Fact. default setting Address	Cust. setting Address

<sup>\*)</sup> Only in part

There is no direct write access to the customer setting values (D200 - D27F) and the factory setting values (D280 - D2FF). These holding registers can only be changed by way of the holding registers Customer Setting Control (see 2.6) and Factory Setting Control (see 2.5).

## **Coding of parameters:**

Unless otherwise stated, parameters are coded in "big endian" format, i.e. the byte with the most significant bits comes first. This applies in particular to parameters covering several holding registers.

#### 2.2 Reset

Address : D000

Write authorization : ebm-papst, customer, end customer

Coding:

MSB	0	0	0	0	0	0	0	0
LSB	0	0	0	0	Reset	Error	Param.	AWS Rst

A bit triggers the following action in the fan when it is set:

Reset : Software reset (incorporates "Reset errors" and "Transfer parameters")

Software is started at the start of the boot loader

Error : Errors are reset

Param. : All parameters are transferred from the EEPROM to the RAM

This bit has to be set to validate changed parameters

Reset AWS : User software reset

(incorporates "Reset errors" and "Transfer parameters") Software is started at the start of the application software

Following implementation of the action the bit is automatically reset by the fan.

On reset (bit 3), the program is re-started at the start of the boot loader. Commands from the master are then neither answered nor executed for a few seconds.

Reset (bit 3) is only recommended if a new application software is to be loaded via the boot loader (on account of break in communication).

The application software reset (bit 0) is recommended if the software is to be merely re-started. There is then no break in communication.

#### 2.3 Set value

Address : D001

Write authorization : ebm-papst, customer, end customer

A set value can be specified for each operating mode via MODBUS using the parameter Set value. This is only possible if RS485 (1) has been specified as "Set value source" (see 2.14 Set value source). Otherwise the parameter has no function.

If the function "Store" is activated in the parameter "Store set value" (see 2.18 Store set value), the value is transferred to the parameter Stored set value with every write-access to the setpoint (see 2.10 Stored set value).

The external input "Parameter set 1/2" or the parameter "Parameter set internal" can be used to select whether the value is stored in "Stored set value (parameter set 1)" or in "Stored set value (parameter set 2)" (see 2.20 Parameter set internal).

After a reset, the motor then starts up again with this value, provided that the parameter set selection has not been changed (see 2.18 Store set value).

#### Attention:

If the function "Store set value" is active and the parameter set is switched (from 1 to 2 or vice versa), the setpoint automatically changes to the value specified in the corresponding parameter "Stored set value (parameter set 1)" or "Stored set value (parameter set 2)".

#### Coding:

Note: The 4 LSBs have no significance for the set value and are always assumed to be 0.

#### a) In speed control operating mode

The set value denotes a speed:

Set value rpm = 
$$\frac{Data\ bytes}{64000} \cdot nMax\ rpm$$

nMax [rpm] ... maximum speed in revolutions per minute (see 2.31 Maximum speed)

The value zero signifies motor standstill

#### b) In open-loop PWM control operating mode

The set value denotes a modulation level:

Set value 
$$\% = \frac{Data\ bytes}{65536} \cdot 100\%$$

The value zero signifies motor standstill

#### c) In closed-loop sensor control operating mode

The set value denotes a sensor quantity:

A sensor which converts the control variable into a voltage of 0..10 V or 4..20 mA must be connected to the fan.

A set value can be entered for the output voltage or output current of the sensor used. The set value for the control variable is then obtained from the set value parameter and the characteristic curve Cv (U/I) of the sensor used.

Cv (U) = Control variable as a function of voltage

Set value 
$$V = \frac{Data\ bytes}{65536} \cdot 10V$$

Set value unit (Cv) = Cv (set value V)  
= 
$$Rg \left( \frac{Data\ bytes}{65536} \cdot 10V \right)$$

or

Cv (I) = Control variable as a function of current

Set value 
$$mA = \frac{Data\ bytes}{65536} \cdot 16mA + 4mA$$

Set value unit(Cv) = 
$$Cv (set \ value \ V)$$
  
=  $Cv (\frac{Data \ bytes}{65536} \cdot 16mA + 4mA)$ 

## 2.4 Password

Address : D002 - D004

Write authorization : ebm-papst, customer, end customer

**Encoding:** 

Password = Data bytes

In order to prevent the unauthorized writing of certain parameters, these will only be written if the correct password for the necessary authorization has been entered at this point.

If a user forgets to reset the password, this will be automatically reset to 0x0000000000 after 4 minutes of inactivity.

When the "Password" parameter is read, the value 0 is always output to prevent a user with a lower authorisation level gaining access to a password to a higher level.

## 2.5 Factory setting Control

Address : D005

Write authorization : ebm-papst, customer (in part)

#### Coding:

MSB	0	0	0	0	0	0	0	0
LSB	0	0	0	0	0	Error	D -> F	F -> D

Setting the bit D -> F causes all the parameters of the data area (D100..D17F) to be copied to the factory setting (area D280..D2FF).

Setting the bit F -> D causes all the parameters of the factory setting (area D280..D2FF) to be copied to the data area (D100..D17F).

On completion of copying, the bit is automatically reset by the fan.

If an error occurs during copying, the "Error" bit is set and copying is terminated

<sup>&</sup>quot;ebm-papst" authorization is required for setting this bit.

<sup>&</sup>quot;Customer" authorization is sufficient for setting this bit.

## **Customer setting Control**

Address : D006

Write authorization : ebm-papst, customer, end customer (in part)

## Coding:

MSB	0	0	0	0	0	0	0	0
LSB	0	0	0	0	0	Error	D -> C	C -> D

Setting the bit D -> C causes all the parameters of the data area (D100..D17F) for which the customer has write authorization to be copied to the customer setting (area D200..D27F). A minimum of "Customer" authorization is required for setting this bit.

Setting the bit C -> D causes all the parameters of the customer setting (area D200..D27F) for which the customer has write authorization to be copied to the data area (D100..D17F). "End customer" authorization is sufficient for setting this bit.

On completion of copying, the bit is automatically reset by the fan.

If an error occurs during copying, the "Error" bit is set and copying is terminated

## Operating hours counter

: D009 Address Write authorization : ebm-papst

Encoding:

Operating time h = Data bytes

After every hour the fan runs, the operating hours counter is incremented by 1 for every hour for which the fan runs. The holding register D180 "Operating hours counter back-up" is simultaneously updated with every change (see 2.57 Operating hours counter (back-up))

A total of max. 65 535 hours (approx. 7.5 years) can be counted with 16 bits. The operating hours counter will no longer be written in the event of an overflow, i.e. it remains on 65 535.

## 2.8 Operating minutes counter

Address : D00A Write authorization : ebm-papst

Encoding:

*Operating minutes min* = *Data bytes* 

After every full minute the fan runs, the operating minutes counter is incremented by 1 for every full minute for which the fan runs.

## 2.9 Addressing on / off

Address : D00C

Write authorization : ebm-papst, customer, end customer

#### Coding:

Value	Function
0x00	Addressing function inactive
0x01	Addressing function active

If the addressing function is active, the signal at the input Din1 is used to change the fan address (see 2.13 Fan address). I/O 1 must be configured as digital input for this (see 2.45)

Every positive edge (transition from "low" to "high") at the digital input Din1 causes the fan address to be incremented by 1. The maximum permissible frequency of the signal is 1.5 Hz (pulse length > 333 ms)

The pulses at the digital input Din1 can be passed on to the next fan at the 0-10 V output. The parameter "Function output 0-10 V" is to be accordingly set for this (see 2.37.1).

The first pulse following activation of the function is not passed on.

#### Attention:

This function has to be deactivated again on completion of addressing

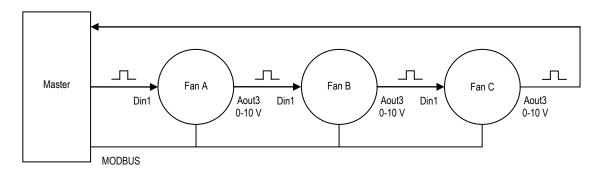

- To transfer the fan address to the non-volatile memory (holding register D100 Fan address, see 2.13)
- To avoid unintentional address changes

Application: Automatic addressing of an installation with the aid of an additional equipment wire

Hardware prerequisites:

Each fan requires a digital input (Din1) and a 0-10 V output (Aout 0-10 V)

## System set-up:

- Fan A is connected to the master via the input Din1
- The 0-10 V output (Aout 0-10 V) of each fan is connected to the input Din1 of the next fan
- The 0-10 V output (Aout 0-10 V) of the last fan (C) is routed back to the master
- All the fans are connected to the master via MODBUS

#### Sequence:

- All the fan addresses are set to the same value (e.g. 1) using a broadcast command.
- The parameter "Function output 0-10 V" of all fans is set to the value 4 Pulses auto addressing using a broadcast command (see 2.37.1).
- The parameter Addressing on / off of all fans is set to the value 1 (active) using a broadcast command.
- The master generates a pulse on the equipment wire.
  - Fan A increments its address to 2.
- The master generates another pulse on the equipment wire.
  - Fan A increments its address to 3 and passes on the pulse to fan B.
  - Fan B increments its address to 2.
- The master generates another pulse on the equipment wire.
  - Fan A increments its address to 4 and passes on the pulse to fan B.
  - Fan B increments its address to 3 and passes on the pulse to fan C.
  - Fan C increments its address to 2.
- The master generates another pulse on the equipment wire.
  - Fan A increments its address to 5 and passes on the pulse to fan B.
  - Fan B increments its address to 4 and passes on the pulse to fan C.
  - Fan C increments its address to 3 and passes on the pulse to the master.
- The master recognizes that the last fan has been addressed and deactivates the addressing function by setting the parameter Addressing on / off of all fans to the value 0 (inactive) using a broadcast command

A similar procedure applies to larger installations. The master continues generating pulses until the last fan sends a pulse back to the master.

#### 2.10 Stored set value

Parameter set 1 address : D00D Parameter set 2 address : D00E

Write authorization : ebm-papst, customer, end customer

The information in these parameters is only of relevance if the value for the parameter "Set value source" is "RS485" (1) (see 2.14 Set value source) and the function "Store set value" is active (see 2.18 Store set value). Otherwise the two parameters have no function.

As the setpoint is located in the volatile memory, this value (if applicable) has to be saved in the non-volatile memory as well to permit restarting with the last setpoint following interruption and restoration of the power supply. The parameter "Stored set value" is intended for this purpose.

If the parameter "Setpoint" is changed, the corresponding parameter "Stored set value (parameter set 1)" or "Stored set value (parameter set 2)" is also automatically set to the same value if the function "Store set value" is active (see 2.3 Set value, 2.18 Store set value).

The parameter "Parameter set internal" or the digital input can be used to select whether the value in "Stored set value (parameter set 1)" or the value in "Stored set value (parameter set 2)" is stored (see 2.20 Parameter set internal).

### Coding:

### a) In closed loop speed control operating mode

Set value 
$$rpm = \frac{Data\ bytes}{64000} \cdot nMax\ rpm$$

nMax [rpm] ... maximum speed in revolutions per minute (see 2.31 Maximum speed)

The value zero signifies motor standstill

### b) In open-loop PWM control operating mode

The set value designates a modulation level:

Set value 
$$\% = \frac{Set \ value}{65536} \cdot 100\%$$

The value zero signifies motor standstill

Note: The 4 LSBs have no significance for the set value and are always assumed to be 0.

### c) In closed loop sensor control operating mode

The set value designates a sensor quantity:

A sensor which converts the control variable into a voltage of 0..10 V or 4..20 mA must be connected to the fan.

A set value can be entered for the output voltage or output current of the sensor used. The set value for the control variable is then obtained from the set value parameter and the characteristic curve Cv (U/I) of the sensor used.

Cv (U) = Control variable as a function of voltage

$$Set \ value \ V \quad = \quad \frac{Data \ bytes}{65536} \cdot 10V$$

Set value unit(Cv) = Cv (Set value V)  
= Cv (
$$\frac{Data\ bytes}{65536} \cdot 10V$$
)

or

Cv (I) = Control variable as a function of current

Set value 
$$mA = \frac{Data\ bytes}{65536} \cdot 16mA + 4mA$$

Set value unit(Cv) = Cv (Set value V)  
= 
$$Cv \left(\frac{Data\ bytes}{65536} \cdot 16mA + 4mA\right)$$

Note: The 4 LSBs have no significance for the set value and are always assumed to be 0.

## 2.11 Enable / Disable

Address : D00F

Write authorization : ebm-papst, customer, end customer

The information in this parameter is only of relevance if the value for "Switch for Enable / Disable source" is 1 (parameter Enable / Disable) (see 2.52). For more information on the Enable signal function, see 2.52

If the function "Store" is activated in the parameter "Store set value" (see 2.18 Store set value), the value will be transferred to the parameter "Stored Enable / Disable" if the power supply is interrupted (see 2.53). Once the power supply has been restored, the value of the parameter "Stored Enable / Disable" will be transferred back to the parameter "Enable / Disable" again.

### Coding:

Value	Enable / Disable
0	Off (no enable)
1	On (enable)

Permissible value range: 0..1

## 2.12 Remote control output 0-10 V

Address : D010

Write authorization : ebm-papst, customer, end customer

Coding:

 $Remote control value = \frac{Data \, bytes}{65536} \cdot 100\%$ 

The information in this parameter is only of relevance if the value for "Function output 0-10 V" is "Remote control" (5) (see 2.37.1).

In this case the voltage at the output 0-10 V is obtained from the remote control value and the output 0-10 V characteristic curve. This characteristic curve assigns a voltage for the analog output to the remote control value: For further information, see 2.37.2 Characteristic curve output 0..10 V

## 2.13 Fan address

Address : D100

Write authorization : ebm-papst, customer, end customer

Coding:

Fanaddress = Databytes(LSB)

The MSB has no significance.

Permissible value range: 1 to 247

## 2.14 Set value source

Address : D101

Write authorization : ebm-papst, customer, end customer

Coding:

This parameter specifies the source of the set value:

Value	Set value source
0	Analog input Ain1
1	RS485 (parameter Set value D001)
2	Analog input Ain2
3	PWM input PWMin3

The MSB has no significance. Permissible value range: 0..3

The information in this parameter is only of relevance if the value for the parameter "Switch for set value source" is "Parameter set value source" (0) - see **Fehler! Verweisquelle konnte nicht gefunden werden.** Switch for set value source

## 2.15 Switch for set value source

Address : D16C

Write authorization : ebm-papst, customer, end customer

Coding:

This parameter specifies whether a digital input or the internal parameter Set value source is used for selection of the set value source.

Value	Set value source is selected by:
0	Parameter Set value source (D101) - see 2.14
1	Digital input Din1
2	Digital input Din2
3	Digital input Din3

The MSB has no significance.

Permissible value range: 0..3

The following table provides an overview of the selected set value source:

Set value source switching	0	0	0	1	1	2	2	3	3
Set value source (D101)	0	1	2	Х	Х	Х	Х	Х	Х
Digital input Din1	X	Х	Х	active	inactive	Х	Х	Х	Х
Digital input Din2	Х	Х	Х	Х	Х	active	inactive	Х	Х
Digital input Din3	Х	Х	Х	Х	Х	Х	Х	active	inactive
Selected set value source	Ain1	RS485	Ain2	Ain2	RS485	Ain1	RS485	Ain1	RS485

For definition of active / inactive: see 2.45

# 2.16 Switch for rotating direction source

Address : D148

Write authorization : ebm-papst, customer, end customer

Coding:

This parameter specifies the sources through which the running direction is determined

Value	Rotating direction source
0	Digital input Din2 and parameter "Preferred running direction"
1	Parameter "Preferred running direction" only
2	Digital input Din3 and parameter "Preferred running direction"
3	Digital input Din1 and parameter "Preferred running direction"

The MSB has no significance.

Permissible value range: 0..3

If just the parameter "Preferred running direction" (1) is selected as running direction source, the actual running direction will correspond to the information in the parameter "Preferred running direction"

If a digital input is selected as running direction source, the actual running direction will correspond to the information in the parameter "Preferred running direction" if the corresponding digital input is inactive. If the digital input is active, the actual running direction will be opposite to that specified in the parameter Preferred running direction.

The following table provides an overview of the actual running direction:

Running direction source	0	0	0	0	1	1
Preferred running	0	0	1	1	0	1
direction						
Digital input Din1	Χ	Χ	Χ	Χ	Χ	Χ
Digital input Din2	active	inactive	active	inactive	X	X
Digital input Din3	X	X	X	X	X	X
Running direction	Clockwise	Counter-	Counter-	Clockwise	Counter-	Clockwise
_		clockwise	clockwise		clockwise	

Running direction	2	2	2	2	3	3	3	3
source								
Preferred running	0	0	1	1	0	0	1	1
direction								
Digital input Din1	X	X	X	X	active	inactive	active	inactive
Digital input Din2	X	X	Х	X	Х	Х	Х	Χ
Digital input Din3	active	inactive	active	inactive	Х	Х	Х	Х
Running direction	Clockwise	Counter-	Counter-	Clockwise	Clockwise	Counter-	Counter-	Clockwise
		clockwise	clockwise			clockwise	clockwise	

For definition of active / inactive: see 2.45

If the fail safe function is active and an interruption in the connection is detected, the direction of rotation is set to the value "Rotating direction fail-safe mode" (see 2.49). The parameter Running direction source is not relevant in this case.

## 2.17 Preferred running direction

Address : D102

Write authorization : ebm-papst, customer, end customer

Coding:

This parameter specifies the preferred running direction

Value	Preferred running direction
0	Counter-clockwise
1	Clockwise

The MSB has no significance.

Permissible value range: 0..1

The new value becomes valid immediately (without reset) after writing this parameter.

The actual running direction is influenced not just by this parameter, but also by "Running direction source" and the digital inputs Din1, Din2 and Din3.

For details of the actual running direction, see 2.16 Switch for rotating direction source

If the fail safe function is active and an interruption in the MODBUS connection is detected, the direction of rotation is set to the value of "Fail safe running direction" (see 2.49). The parameter Preferred running direction is not relevant in this case.

### 2.18 Store set value

Address : D103

Write authorization : ebm-papst, customer, end customer

Coding:

This parameter specifies whether

- The set value (see 2.3) is additionally stored in the Stored set value (see 2.10)
- The parameter Enable / Disable (see 2.11) is additionally stored in the parameter Stored Enable / Disable (see 2.53) in the event of an interruption of the power supply.

Value	Function
0	Set value and Enable / Disable are not stored
	The fan does not run after switching on the power supply or following reset
1	Set value and Enable / Disable are stored
	The fan runs with the stored set value and Enable / Disable state after switching on the power
	supply or following reset

The MSB has no significance. Permissible value range: 0..1

# 2.19 Switch for parameter set source

Address : D104

Write authorization : ebm-papst, customer, end customer

Coding:

This parameter specifies whether a digital input or the internal parameter is used for selection of the parameter set.

Value	Parameter set switching by
0	Digital input Din2
1	Parameter "Parameter set internal" (see 2.20 Parameter set internal)
2	Digital input Din3
3	Digital input Din1

The MSB has no significance.

Permissible value range: 0..3

The following table provides an overview of the selected parameter set:

Parameter set source	0	0	1	1	2	2	3	3
Parameter set internal	Х	Х	0	1	Х	Х	Х	Х
Digital input Din1	Х	Х	Х	Х	Х	Х	active	inactive
Digital input Din2	active	inactive	Х	Х	Х	Х	Х	Х
Digital input Din3	X	X	X	X	active	inactive	X	Χ
Selected parameter	2	1	1	2	2	1	2	1
set								

For definition of active / inactive: see 2.45

## 2.20 Parameter set internal

Address : D105

Write authorization : ebm-papst, customer, end customer

Coding:

This parameter specifies whether parameter set 1 or parameter set 2 is used.

The information in this parameter is only of relevance if the value for "Switch for parameter set source" is "internal" (1) (see 2.19 Switch for parameter set source).

Value	Parameter set
0	Parameter set 1
1	Parameter set 2

The MSB has no significance.

Permissible value range: 0..1

The new value becomes valid immediately (without reset) after writing this parameter.

## 2.21 Operating mode

Parameter set 1 address : D106 Parameter set 2 address : D107

Write authorization : ebm-papst, customer, end customer

The parameter "Parameter set internal" or the digital input can be used to select whether the value in "Operating mode (parameter set 1)" or the value in "Operating mode (parameter set 2)" has validity (see 2.20 Parameter set internal).

### Coding:

Value	Operating mode
0	Closed-loop speed control
1	Sensor control
2	Open-loop PWM control

The MSB has no significance.

Permissible value range: 0..2

### 2.22 Switch for controller function source

Address : D12E

Write authorization : ebm-papst, customer, end customer

Coding:

This parameter specifies whether a digital input or the internal parameter is used for selection of the controller function.

Value	Determination of controller function by
0	Digital input Din3
1	"Controller function" parameter (see 2.23 Controller function)
2	Digital input Din2
3	Digital input Din1

The MSB has no significance.

Permissible value range: 0..3

The following table provides an overview of the selected controller function:

Source for controller	0	0	1	1	2	2	3	3
function								
Controller function	X	X	0	1	X	X	X	X
Digital input Din1	X	Х	X	Х	Х	Х	active	inactive
Digital input Din2	X	X	X	X	active	inactive	X	X
Digital input Din3	active	inactive	X	X	X	X	X	X
Selected controller	Negative	Positive	Positive	Negative	Negative	Positive	Negative	Positive
function							· ·	

For definition of active / inactive: see 2.45

### 2.23 Controller function

Parameter set 1 address : D108 Parameter set 2 address : D109

Write authorization : ebm-papst, customer, end customer

The parameter "Parameter set internal" or the digital input can be used to select whether the value in "Controller function (parameter set 1)" or the value in "Controller function (parameter set 2)" is applicable (see 0 Parameter set internal).

The information in these parameters is only of relevance if the value for the parameter "Switch for controller function source" is "internal" (1) (see 2.22 Switch for controller function source). Otherwise the two parameters have no function.

The controller function specifies how the deviation is formed from the set value and the actual value

## Coding:

Value	Controller function
0	Positive: Deviation = Set value - Actual value

## 1 Negative: Deviation = Actual value - Set value

The MSB has no significance.

A positive controller function means that the modulation level of the fan decreases with an increasing actual value.

A negative controller function means that the modulation level of the fan increases with an increasing actual value.

#### Notes:

For closed-loop sensor control with a temperature sensor a positive controller function is synonymous with "Heating" and a negative controller function is synonymous with "Cooling".

Only a positive controller function is appropriate in "Closed loop speed control" operating mode. For this reason, the parameter "Controller function" has no function in the "Closed-loop speed control" operating mode and is always assumed to be positive.

## 2.24 Control parameters

2 control parameters are provided for closed loop speed control and closed loop sensor control:

- P factor kp
- I factor ki

P factor (parameter set 1) address : D10A
P factor (parameter set 2) address : D10B
I factor (parameter set 1) address : D10C
I factor (parameter set 2) address : D10D

Write authorization : ebm-papst, customer, end customer

The parameter "Parameter set internal" or the digital input can be used to select whether the values in "P factor / I factor (parameter set 1)" or the values in "P factor / I factor (parameter set 2)" have validity (see 2.20 Parameter set internal).

#### Coding:

Each control parameter is made up of 2 bytes.

a) P factor

$$P \ factor = \frac{Data \ bytes}{256} \cdot 100\%$$

This means that values can thus be set between 0 and 25,600% for the P factor, in increments of 0.39%

b) I factor

$$I \ factor = \frac{Data \ bytes}{65536} \cdot 100\%$$

This means that values Values between 0 and 100% can thus be set for the I factor in increments of 0.00153%

### Notes on control action:

On completion of the sampling time T<sub>a</sub> = 50 ms, the fan controller always calculates the new modulation level in accordance with the following equation:

$$a(n) = \frac{kp}{100\%} \cdot xd(n) + \sum_{i=0}^{n} \frac{ki}{100\%} \cdot xd(i)$$

a(n).......Modulationlevel at time n; normalized to range 0..65536, i.e. 65536->100%

xd(n)......Normalized deviation at time n (set value - actual value)

kp......P factor in %

ki.....I factor in %

The normalized deviation is calculated from the set value and the actual value.

The set value and the actual value are also normalized:

- To the maximum speed in speed control
- To the minimum and maximum sensor value in sensor control

The normalized controller equation above and the generally applicable controller equation

$$A(n) = kr \cdot \left( Xd(n) + \frac{Ta}{Tn} \sum_{i=0}^{n} Xd(i) \right)$$

A(n)......Modulationlevel at time n (0..100%)

Xd(n)......Absolute deviation at time n (set value - actual value)

kr.....Proportional action coefficient

Tn.....Integraltime

Ta.....Samplingtime

... can be transformed into one another as follows

$$kr = \frac{kp}{\textit{Reference value Max - Reference value Min}} \quad or \quad kp = kr \cdot (\textit{Reference value Max - Reference value Min})$$

$$Tn = \frac{kp}{ki} \cdot Ta \quad or \quad ki = \frac{Ta}{Tn} \cdot kr \cdot (\textit{Reference value Max - Reference value Min})$$

where

$$Ta = 50ms$$

In closed loop speed control operating mode:

 $Reference value Max = 1.024 \cdot nMax$ 

Reference value Min = 0

*nMax* ..... *Max*. *speed* [rpm]

In sensor control operating mode:

Reference value Max = Max sensor value

Reference value Min = Min sensor value

Max sensor value ......Sensor quantity for U = 10V

Min sensor value ......Sensor quantity for U = 0V

## 2.25 Maximum modulation level

Parameter set 1 address : D10E Parameter set 2 address : D10F

Write authorization : ebm-papst, customer

The parameter "Parameter set internal" or the digital input can be used to select whether the value in "Maximum modulation level (parameter set 1)" or the value in "Maximum modulation level (parameter set 2)" has validity (see 2.20 Parameter set internal).

## Coding:

**Encoding:** 

Max. modulation level 
$$\% = \frac{Data\ bytes}{256} \cdot 100\%$$

The MSB has no significance.

#### Limitation:

8% < Maximum modulation level < Maximum permissible modulation level (see 2.29 Maximum permissible modulation level).

#### 2.26 Minimum modulation level

Parameter set 1 address : D110 Parameter set 2 address : D111

Write authorization : ebm-papst, customer, end customer

The parameter "Parameter set internal" or the digital input can be used to select whether the value in "Minimum modulation level (parameter set 1)" or the value in "Minimum modulation level (parameter set 2)" has validity (see 2.20 Parameter set internal).

#### **Encoding:**

Min. modulation level 
$$\% = \frac{Data\ bytes}{256} \cdot 100\%$$

The MSB has no significance.

#### Limitation:

Minimum modulation level > Minimum permissible modulation level (see 2.30 Minimum permissible modulation level).

## 2.27 Motor stop enable

Parameter set 1 address : D112 Parameter set 2 address : D113

Write authorization : ebm-papst, customer, end customer

The parameter "Parameter set internal" or the digital input can be used to select whether the value in "Motor stop enable (parameter set 1)" or the value in "Motor stop enable (parameter set 2)" has validity (see 2.20 Parameter set internal).

#### Coding:

Value	Motor stop
0	Motor always runs (even with set value = 0)
1	Motor stops with set value = 0

The MSB has no significance.

# 2.28 Starting modulation level

Address : D116 Write authorization : ebm-papst

The starting modulation level specifies the modulation level with which the motor is started after a start command.

Encoding:

Starting modulation level 
$$\% = \frac{Data\ bytes}{256} \cdot 100\%$$

The MSB has no significance.

The motor always starts with the starting modulation level.

A high starting modulation level results in a high current on starting the motor.

## 2.29 Maximum permissible modulation level

Address : D117 Write authorization : ebm-papst

This parameter forms the upper limit for the maximum modulation level (see 2.25 Maximum modulation level).

Encoding:

Max. perm. modulation level 
$$\% = \frac{Data\ bytes}{256} \cdot 100\%$$

The MSB has no significance.

## 2.30 Minimum permissible modulation level

Address : D118 Write authorization : ebm-papst

This parameter forms the lower limit for the minimum modulation level (see 2.26 Minimum modulation level).

## Encoding:

Min. perm. modulation level 
$$\% = \frac{Data\ bytes}{256} \cdot 100\%$$

The MSB has no significance.

If the setting selected for this value is too low (in particular values < 5%), the motor may cut out with the error "Motor blocked".

## 2.31 Maximum speed

Address : D119

Write authorization : ebm-papst, customer

This parameter has two functions:

- All parameters with speed information (set values, actual values) are referenced to this value.
   The value 64000 in this speed information corresponds to the maximum speed value specified here.
- In the control modes "Closed-loop sensor control" and "Open-loop PWM control", the speed is limited to the value specified here (the speed is controlled in any case in Closed-loop speed control).

### Encoding:

$$Max. speed rpm = Data bytes$$

The maximum speed is made up of 2 bytes.

#### Limitation:

Maximum speed < Maximum permissible speed (see 2.32 Maximum permissible speed)

## 2.32 Maximum permissible speed

Address : D11A Write authorization : ebm-papst

This parameter forms the upper limit for the maximum speed (see 2.31 Maximum speed).

### Encoding:

Max. perm. speed rpm = Data bytes

The maximum permissible speed is made up of 2 bytes.

# 2.33 Ramp-up curve / ramp-down curve

Ramp-up curve address : D11F Ramp-down curve address : D120

Write authorization : ebm-papst, customer, end customer

The parameters Ramp-up curve and Ramp-down curve define the time in which the active set value is corrected to the new set value.

The time for the ramp-up curve relates to a step-change in the setpoint from 0 to the maximum value (coded 64000).

The time for the ramp-down curve relates to a step-change in the setpoint from the maximum value (coded 64000) to 0.

If a motor stop condition is detected (e.g. setpoint = 0 and motor stop enable = 1), the motor comes to a stop without following the ramp-down curve.

A new set value with no time delay takes immediate effect for ramp time = 0.

## Coding:

 $Ramp\ time\ s = Data\ bytes \cdot 2.5s$ 

The MSB has no significance.

## 2.34 Speed limit

Address : D128 Write authorization : ebm-papst

This parameter determines the limit value for the safety function "Speed limit". The speed controller of this safety function ensures that the speed limit for the fan impeller is not exceeded.

#### **Encoding:**

Limit speed rpm = Data bytes

Note: The speed limit is not referenced to the maximum speed.

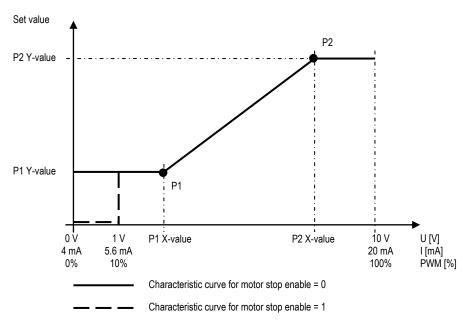

## 2.35 Input characteristic curve

Point 1 X-coordinate parameter set 1 address Point 1 Y-coordinate parameter set 1 address Point 2 X-coordinate parameter set 1 address Point 2 Y-coordinate parameter set 1 address	: D12A : D12B : D12C : D12D
Point 1 X-coordinate parameter set 2 address Point 1 Y-coordinate parameter set 2 address Point 2 X-coordinate parameter set 2 address Point 2 Y-coordinate parameter set 2 address	: D13C : D13D : D13E : D13F

Write authorization : ebm-papst, customer, end customer

These parameters are used to allocate a set value to the input signal. Possible input signals:

- Voltage at analog input Ain1
- Voltage or current at analog input Ain2
- PWM modulation level at PWM input PWMin3

Points P1 and P2 can be shifted to anywhere in the graph.

2 different characteristic curves can be defined.

The parameter "Parameter set internal" or the digital input can be used to select whether the values "Parameter set 1" or the values "Parameter set 2" have validity (see 2.20 Parameter set internal).

## Coding:

#### X-coordinate:

The coding of the X-coordinate depends on the configuration of the I/O (see 2.45) for the set value.

### a) Analog input 0-10 V

$$UV(Px) = \frac{Data\ byte}{65536} \cdot 10\ V$$

The X-coordinate defines a voltage value between 0 and 10 V.

#### b) Analog input 4-20 mA

$$I \, mA \, (Px) = \frac{Data \, byte}{65536} \cdot 16mA + 4mA$$

The X-coordinate defines a current value between 4 and 20 mA.

### c) PWM input

$$PWM\%(Px) = \frac{Data\ byte}{65536} \cdot 100\%$$

The X-coordinate defines a PWM modulation level between 0 and 100%.

#### Y-coordinate:

The Y-coordinate defines the corresponding set value for this point. Depending on the operating mode (see 2.21), it is a speed (closed-loop speed control), a sensor quantity (closed loop sensor control) or a modulation level (open-loop PWM control).

## a) closed-loop speed control:

Set value 
$$rpm = \frac{Data\ byte}{64000} \cdot nMax\ rpm$$

nMax rpm ... maximum speed in revolutions per minute (see 2.31 Maximum speed)

### b) In open-loop PWM control operating mode

Set value 
$$\% = \frac{Data\ byte}{65536} \cdot 100\%$$

### c) In closed-loop sensor control operating mode

The set value for the control variable is then obtained from the set value parameter and the characteristic curve Cv (U/I) of the sensor used.

Cv (U) = Control variable as a function of voltage

$$Set \ value \ V \quad = \quad \frac{Data \ byte}{65536} \cdot 10V$$

Set value unit(Cv) = Cv (Set value V)  
= 
$$Cv \left( \frac{Data\ byte}{65536} \cdot 10V \right)$$

or

Cv (I) = Control variable as a function of current

Set value 
$$mA = \frac{Data\ byte}{65536} \cdot 16mA + 4mA$$

Set value unit(Cv) = 
$$Cv$$
 (Set value V)  
=  $Cv$  ( $\frac{Data\ byte}{65536} \cdot 16mA + 4mA$ )

For voltages at the analog input which are lower than the value defined in the X-coordinate of point 1, the set value is the value defined in the Y-coordinate of point 1.

For voltages at the analog input which are higher than the value defined in the X-coordinate of point 2, the set value is the value defined in the Y-coordinate of point 2.

Between these, the set value changes linearly between the two values specified in the Y-coordinates (see graph above).

#### Limitation:

X-coordinate (point 1)  $\leq$  X-coordinate (point 2)

#### Note:

If Y-coordinate (point 1) > Y-coordinate (point 2) is selected, the slope of the characteristic curve will be negative.

In this case the motor stop function takes effect at a voltage at the analog input > 9 V

## 2.36 Control limitation

Address : D12F

Write authorization : ebm-papst

This parameter defines which limitation functions are activated.

## Coding:

MSB	0	0	0	0	0	Reserved	Reserved	Reserved
LCD	0	0	0	0	Reserved	Reserved		Ь
LSB	U	O	O	U	Keserveu	Keserveu		٢

The MSB is of no relevance!

I ...... Coil current limitation

P ...... Power limiter

## 2.37 Function output 0..10 V / speed monitoring

## 2.37.1 Function output 0..10 V / speed monitoring

Function address : D130

Write authorization : ebm-papst, customer

This parameter determines

Which quantity is output at the output (LSB)

The number of pulses output per revolution at the output (MSB)

#### LSB coding:

Value	Output quantity
0	Fan modulation level
1	Actual speed
2	Installation modulation level
4	Pulses auto addressing
5	Remote control

In order to be able to output one of these quantities at the analog output, IO3 must be configured as analog output (see 2.45)

#### Applications:

a) Fan modulation level -> 0..10 V (value = 0)

With this configuration, the specified modulation level is output at the 0..10 V output. This signal can be connected to the set value input of other fans, which then run at the same modulation level. In the event of an error, a modulation level of 0% is always output.

b) Actual speed -> 0..10 V (value = 1)

With this configuration, a voltage proportional to the speed is output at the 0..10 V output. The value 10 V is then attained for a speed n = 1.02 \* nMax

The signal can be used to evaluate the actual speed.

c) Installation modulation level -> 0..10 V (value = 2)

With this configuration, the specified modulation level is output at the 0..10 V output. This signal can be connected to the set value input of other fans, which then run at the same modulation level. In the event of an error at the fan, a modulation level is still output at the 0..10 V output as if no error had occurred. This has the advantage that the other fans in the installation are still controlled despite an error at the master fan.

Explanatory notes on the installation modulation level:

- This setting is not appropriate in "Closed loop speed control" operating mode, as no speed information for the other fans is available at the master fan and control action is thus not possible in the event of an error.
- In "Closed loop sensor control" operating mode, controller function continues to be based on the sensor quantity and the modulation level is output at the 0..10 V output in the event of an error.
- In "Open-loop PWM control" operating mode, the specified modulation level continues to be output at the 0..10 V output in the event of an error.
- Once there is no longer an error at the master fan, output of the modulation level of the master fan at the 0..10 V output is resumed again. As this is generally increased from 0% upwards in a ramp function, the same profile will also be set at the output of the 0..10 V output so that the entire installation will be briefly shut down.
- d) Pulses auto addressing -> 0..10 V (value = 4)

The (clock) signal for the addressing function (see 2.9) at the digital input Din1 is output at the 0-10 V output. The first clock pulse following activation of the addressing function is not passed on.

The parameters of the output characteristic curve 0-10 V (see 2.37.2) have no effect in this configuration.

e) Remote control -> 0..10 V (value = 5)

The parameter Remote control output 0-10 V (see 2.12) can be used to specify a value for the voltage at the 0-10 V output irrespective of the modulation level, speed, etc.

### MSB coding:

Number of pulses per revolution = Databyte

A frequency proportional to the speed is output at the tach output. The number of pulses per revolution can be selected. The signal can be used to evaluate the actual speed.

To be able to output speed monitoring (pulses per revolution), IO1 or IO3 must be configured as tach output (see 2.45)

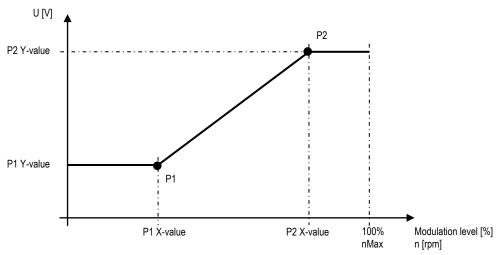

## 2.37.2 Characteristic curve output 0..10 V

Point 1 X-coordinate address : D140 Point 1 Y-coordinate address : D141 Point 2 X-coordinate address : D142 Point 2 Y-coordinate address : D143

Write authorization : ebm-papst, customer, end customer

These parameters are used to allocate a voltage to the output quantity defined by the parameter "Function output 0..10 V" at the output 0..10 V.

## The parameter is only relevant if signal type "0 to 10V" is selected (see 2.37.1)

Points P1 and P2 can be shifted to anywhere in the graph.

## Coding:

## Function output 0..10 V = Modulation level (0 / 2)

The X-coordinate defines a modulation level

Modulation level % 
$$(Px) = \frac{Data\ bytes}{65536} \cdot 100\%$$

### Function output 0..10 V = Actual speed (1)

The X-coordinate defines a speed

$$n \ rpm (Px) = \frac{Data \ bytes}{64000} \cdot nMax$$

nMax rpm ... maximum speed in revolutions per minute (see 2.31 Maximum speed)

### Function output 0..10 V = Remote control (5)

The X-coordinate defines the remote control value

Remote control value % 
$$(Px) = \frac{Data\ bytes}{65536} \cdot 100\%$$

The Y-coordinate defines the corresponding voltage at the 0..10 V output:

$$UV(Px) = \frac{Data\ byte}{65536} \cdot 10V$$

#### Limitation:

X-coordinate (point 1)  $\leq$  X-coordinate (point 2)

## **Applications:**

A characteristic curve with the following values is recommended

P1X = 0x0000 0% / 0 rpm

P1Y = 0x0000 0 V

 $P2X = 0xFF00 \ 100\% / 1.02 * nMax$ 

P2Y = 0xFF00 10 V

In this case:

$$U_{0..10V}V = \frac{Modulation level (spec.) \%}{100} \cdot 10V$$

or:

$$U_{0..10V}V = \frac{n \ Act \ rpm}{1.02 \cdot n \ Max \ rpm} \cdot 10V$$

nMax [rpm] ... maximum speed in revolutions per minute (see 2.31 Maximum speed)

$$U_{0..10V}V = \frac{Remote\ control\ value\ (spec.)\ \%}{100} \cdot 10V$$

Cascaded start-up of the motors can be obtained by shifting the characteristic curve downwards in parallel.

## 2.38 Power limiter

The fan contains a power limiter. This power limiter is activated if the function has been activated in the parameter "Limitation Control" (see 2.36 Control).

The set value P<sub>Lim,Set</sub> of the power limiter is obtained from the parameters described in the following as a function of the temperature.

## 2.38.1 Maximum power

Maximum power address : D155

Write authorization : ebm-papst, customer

Coding:

$$P \max W = \frac{Data \, byte}{256} \cdot Reference \, Uz \, V \cdot Reference \, Iz \, A$$

P max ..... Maximum power

Reference Uz ..... DC-link voltage reference value (see 2.59 DC-link voltage reference value). Reference Iz ..... DC-link current reference value (see 2.60 DC-link current reference value)

The MSB has no significance.

Limitation:

Maximum power ≤ Maximum permissible power (see 2.38.2 Maximum permissible power)

## 2.38.2 Maximum permissible power

Maximum permissible power address D135

Write authorization : ebm-papst

**Encoding:** 

$$P \max, perm W = \frac{Data \ byte}{256} \cdot Reference \ Uz \ V \cdot Reference \ Iz \ A$$

P max, perm ..... Maximum permissible power

Reference Uz ...... DC-link voltage reference value (see 2.59 DC-link voltage reference value).

Reference Iz ...... DC-link current reference value (see 2.60 DC-link current reference value)

The MSB has no significance.

This parameter forms the upper limit for the maximum power (see 2.38.1) and the max. power at derating end (see 2.38.3)

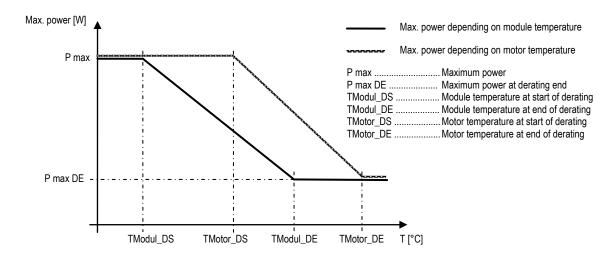

### 2.38.3 Power derating

Max. power at derating end address : D136 Module temperature power derating start address : D137 Module temperature power derating end address : D138 Motor temperature power derating start address : D14D Motor temperature power derating end address : D14E

Write authorization : ebm-papst, customer

The maximum power decreases as a function of the module temperature (see 3.13 Module temperature) and the motor temperature (see 3.14 Motor temperature) in accordance with the following characteristic curves. A separate characteristic curve can be defined for each temperature.

These characteristic curves thus yield

- A max. power value as a function of the module temperature ( $P_{\text{Lim,Set}}$ TModule)
- A max. power value as a function of the motor temperature (P<sub>Lim.Set</sub>\_TMotor)

The lower of the two values P<sub>Lim,Set</sub>\_TModule and P<sub>Lim,Set</sub>\_TMotor is used as set value for the power limiter.

### Encoding:

$$P \max_{DE} W = \frac{\text{Data bytes}}{256} \cdot \text{Reference } Uz V \cdot \text{Reference } Iz A$$

 $TModul \_DS \circ C = Data bytes$  $TModul \_DE \circ C = Data bytes$  $TMotor \_DS \circ C = Data bytes$  $TMotor\_DE \circ C = Data bytes$ 

P max DE..... Maximum power at derating end

Reference Uz ........... DC-link voltage reference value (see 2.59 DC-link voltage reference value). Reference Iz ............ DC-link current reference value (see 2.60 DC-link current reference value)

TModule DS ..... Module temperature power derating start TModule DE ..... Module temperature power derating end TMotor DS ....... Motor temperature power derating start TMotor DE ...... Motor temperature power derating end

The MSB has no significance in each case.

The values "Max. power" and "Max. power at temperature derating end" are the same for both characteristic curves.

For temperatures lower than the value defined in TModule DS or TMotor DS, the maximum power corresponds to the value P max.

For temperatures higher than the value defined in TModule DE or TMotor DE, the maximum power corresponds to the value P max DE.

Between these, the maximum power changes linearly between the two values P max and P max DE (see graph above).

#### Limitation:

If T DS ≥ T DE, T DS is limited to T DE If P max DE >  $P_{max}$  or  $P_{max perm}$ , P max DE is limited to  $P_{max}$  or  $P_{max perm}$ 

#### 2.38.4 Power derating ramp

Address : D16D

Write authorization : ebm-papst, customer

For steep temperature characteristic curves, a change in temperature of just 1K is sufficient to produce a considerable change in the set value of the power limiter P<sub>Lim.Set</sub>, which can lead to considerable variation in the action of the power limiter. To stop this happening, this parameter can be used to specify the maximum change in the set value for the power limiter.

### Coding:

The change in the set value of the power limiter per second is:

$$\Delta P_{Lim, Set} / \sec W / s = \frac{0.078125}{Data \, bytes} \cdot Reference \, Uz \, V \cdot Reference \, Iz \, A$$

Reference Uz ........... DC-link voltage reference value (see 2.59 DC-link voltage reference value). Reference Iz ...... DC-link current reference value (see 2.60 DC-link current reference value)

For data byte = 0, the set value is adopted directly from the temperature characteristic curve without a ramp

When the device is switched on, the set value is directly set to the value determined from the temperature characteristic curve (initial value).

# 2.39 Maximum winding current

Address : D13B Write authorization : ebm-papst

Encoding:

$$I \text{ max, eff } A = \frac{Data \text{ bytes}}{170} \cdot Reference \text{ Iz } A$$

Ref. Iz ...... DC-link current reference (see 2.60 DC-link current reference value)

The MSB has no significance.

The motor limits the winding current (rms value) to the value specified here if the function has been activated in the parameter "Limitation Control" (see 2.36 Control).

The winding current is obtained from the DC-link current / modulation level

## 2.40 Run monitoring speed limit

Address : D145

Write authorization : ebm-papst, customer

Coding:

The speed limit for run monitoring is obtained from the parameter and the maximum speed:

Run monitoring speed limit 
$$rpm = \frac{Data\ bytes}{64000} \cdot nMax\ rpm$$

nMax rpm ... maximum speed (in revolutions per minute) - see 2.31 Maximum speed

If the actual speed (see 3.8 Actual speed) is lower than the run monitoring speed limit, the flag "n\_Low" is set in the input register "Warning" (see 3.10 Warning)

The entire function is deactivated if "Run monitoring speed limit" = 0.

## 2.41 Sensor actual value source

Address : D147

Write authorization : ebm-papst, customer, end customer

Coding:

The parameter "Sensor actual value source" defines the input from which the sensor actual value (see 3.19 Sensor actual values) is determined.

The following options are available:

Value	Sensor actual value source
0x00	Analog input Ain1
0x01	Analog input Ain2
0x02	Maximum (Ain1; Ain2)
0x03	Minimum (Ain1; Ain2)
0x04	Mean value (Ain1; Ain2)

The MSB has no significance.

# 2.42 Interface settings

### 2.42.1 Communication speed

Address : D149

Write authorization : ebm-papst, customer

## Coding:

Value	Transmission speed
0x00	1200 bits/sec
0x01	2400 bits/sec
0x02	4800 bits/sec
0x03	9600 bits/sec
0x04	19200 bits/sec
0x05	38400 bits/sec
0x06	57600 bits/sec
0x07	115200 bits/sec

The MSB has no significance.

The standard value 19200 bits/sec (0x04) is recommended for the transmission speed.

It must be ensured that the transmission speed selected for the fan is the same as that in the master (e.g. EC-Control). Communication with the fan is otherwise not possible.

If the value of the customer setting (holding register D249) or the factory setting (holding register D2C9) differs from the value selected here, it must be ensured that the transmission speed has been accordingly altered following completion of data transfer from the customer setting or factory setting (see 2.5 and 2.6). Communication is then no longer possible with the previous setting

### 2.42.2 Parity configuration

Address : D14A

Write authorization : ebm-papst, customer

## Coding:

Value	Parity configuration	Number of data bits	Parity	Number of stop bits
0x00	8E1	8	Even	1
0x01	801	8	Odd	1
0x02	8N2	8	None	2
0x03	8N1	8	None	1

The MSB has no significance.

The standard value 8E1 (0x00) is recommended for the parity configuration.

Note:

If parity configuration 8N1 is selected, the device no longer corresponds to the MODBUS specification "MODBUS over Serial Line Specification & Implementation Guide V1.0", as this specifies a mandatory 11-bit frame.

It must be ensured that the parity configuration selected for the fan is the same as that in the master (e.g. EC-Control). Communication with the fan is otherwise not possible.

If the value of the customer setting (holding register D24A) or the factory setting (holding register D2CA) differs from the value selected here, it must be ensured that the parity configuration has been accordingly altered following completion of data transfer from the customer setting or factory setting (see 2.5 and 2.6). Communication is then no longer possible with the previous setting.

## 2.42.3 Procedure for changing interface setting

Communication is not possible if the parameters "Communication speed" and "Parity configuration" do not correspond to the setting for the interface in the master (e.g. EC-Control).

If the setting differs, the interface setting cannot be polled from the fan, i.e. it is essential to know the interface setting of the fan.

To avoid complications resulting from different interface settings, it is advisable to leave the interface settings on the default values:

Transmission rate : 19200 bits/sec (0x04)

Parity configuration : 8E1 (0x00)

If a change is necessary, care must be taken to ensure that the master and fan always have the same setting so as to ensure faultless communication.

The new interface setting of the fan is only adopted following a corresponding command to the parameter "Reset" (Transfer parameter or Reset) - see 2.2 - or after switching off the device ("Power off"). Until then the fan operates with the existing setting.

Recommended procedure for changing the interface setting, based on the example of a change from 19200 bits/sec, 8E1 to 38400 bits/sec, 8N2:

- To start with, the interface setting at the master must be 19200 bits/sec, 8E1.
- Write password: XX 10 D0 02 00 03 06 PP PP PP PP PP PP CS CS (The minimum authorization required for changing the interface setting is "Customer")
- Write transmission speed with value 38400 bits/sec: XX 06 D1 49 00 05 CS CS
- Write parity configuration with value 8N2: XX 06 D1 4A 00 02 CS CS
- Trigger Transfer parameter: XX 06 D0 00 00 02 CS CS
- Following acknowledgment of the command by the fan, it will operate with the new setting.
- Change interface setting in master: 38400 bits/sec, 8N2

XX	Fan address
PP	Password
CS	CRC checksum

## 2.42.4 Interface emergency function:

Two standard settings for the interface are stored in the fan.

The fan briefly switches automatically to these standard settings if faulty telegrams are received (e.g. on account of different interface settings at the master and slave):

- After 10 unsuccessful attempts, the fan automatically communicates with the setting 19200 bits/sec, 8E1
- After a further 10 unsuccessful attempts, the fan automatically communicates with the setting 2400 bits/sec, 8E1
  - Exception: This step is omitted with the configuration 115200 bits/sec.
- After another 10 unsuccessful attempts, the fan switches back to the setting stored in the holding registers "Communication speed" and "Parity configuration" to avoid inadvertent permanent activation of the interface emergency function.
- In the event of yet more unsuccessful attempts, the interface is no longer automatically switched, i.e. the
  interface emergency function can then only be activated by switching the device off and on again or by
  way of a software reset

The interface emergency function can only be activated as long as no valid telegram has been detected by the fan. To ensure that the interface emergency function has been enabled, the device operating voltage should be switched off and on again beforehand.

## Application:

If the interface setting of the fan is not known, it can be determined using an interface emergency function.

## Recommended sequence:

- Switch on the fan
- Set the interface of the master to standard values 19200 bits/sec, 8E1
- Read interface setting: XX 03 D1 49 00 02 CS CS
- After 10 unsuccessful attempts, the fan automatically communicates with the standard setting 19200 bits/sec, 8E1. In other words, the above-mentioned command has to be sent 11 times before a response is sent by the fan.
- The interface setting of the fan can be determined from the fan response.
- The master and slave interface settings can then be matched to one another.

## Note:

The fan should not be permanently operated in the interface emergency function, as the values defined in the parameters "Communication speed" and "Parity configuration" are activated again after every "Reset" or "Transfer parameter" (c.f. 2.2).

The master and fan interface settings must always be matched to one another.

## 2.43 Shedding function

Shedding function address : D150

Write authorization : ebm-papst, customer

Max.. start PWM shedding address : D151

Write authorization : ebm-papst

Max. number of starting attempts address : D152

Write authorization : ebm-papst, customer

## Coding:

## a) Shedding function

Value	Shedding function
0	Inactive
1	Active

The MSB has no significance. Permissible value range: 0..1

b) Max. start PWM shedding:

Max. start PWM shedding 
$$\% = \frac{Data\ byte}{256} \cdot 100\%$$

The MSB has no significance.

c) Number of starting attempts

*Max. number of start attempts* = Data byte

The MSB has no significance.

#### Function:

The purpose of the shedding function is to make it possible to shake free the rotor of a fan with frozen blades by implementing alternating starting attempts in both directions of rotation, with the modulation level being increased on each attempt.

The first attempt starts with the value specified in the parameter Starting modulation level (see 2.28 Starting modulation level) and the desired direction of rotation. If this does not manage to make the fan turn, the direction of rotation is reversed in each subsequent attempt and the Starting modulation level is increased by 5% up to a maximum of the "Max. start PWM shedding" value. At the same time a "Shedding function active" warning is generated (see 3.10 Warning).

This process is continued until the number of attempts specified in the parameter "Max. number of starting attempts" has been reached. If the fan has then still not been made to turn, the error message "Motor blocked" (see 3.9 Motor status) is generated. If further starting attempts are made, the modulation level is reset back to the value specified in the parameter "Starting modulation level" and no longer increased.

# 2.44 Relay drop-out delay

Address : D153

Write authorization : ebm-papst, customer, end customer

In the event of an error, relay drop-out is delayed by the time specified here.

Coding:

Relay drop - out delay s = Data byte

The MSB has no significance.

# 2.45 Configuration I/O

#### 2.45.1 Parameters

Configuration I/O 1 address : D158 Configuration I/O 2 address : D159 Configuration I/O 3 address : D15A

Write authorization : ebm-papst, customer, end customer

## Coding:

Value	Function I/O		Availability	
		I/O 1	I/O 2	I/O3
0	Digital input (high active)	Х	Х	Х
1	Digital input (low active)	-	-	Х
2	Analog input 0-10 V	Х	Х	-
3	Analog input 4-20 mA	-	Х	-
4	Analog output 0-10 V	-	-	Х
5	Tach output	Х	-	Х
6	Diagnostic output	Х	-	X
7	PWM input	-	-	Х

Permissible value range:

Only the functions marked with X may be selected for each I/O.

The other functions are not available for the I/O concerned.

Function:

Digital input

Digital inputs are used for the functionality of the parameters

- Switch for set value sourceFehler! Verweisquelle konnte nicht gefunden werden. (see Fehler!
   Verweisquelle konnte nicht gefunden werden.)
- Switch for rotating direction source (see 2.16)
- Switch for parameter set source (see 2.19)
- Switch for controller function source (see 2.22)
- Switch for Enable / Disable input source (see 2.52)

If a digital input is selected as source for one of these parameters, the corresponding I/O must be configured as digital input here.

There are two configuration possibilities for the digital inputs:

Digital input high active (0):

An integrated pull down is connected to the digital input.

So, there is always a defined a logic state, even if the digital input is not connected.

An open input corresponds to a potential of U = 0V and the logical state "inactive".

By applying a voltage U ≥ 3.5 V, the digital input can be switched to the logical state "active".

Digital input low active (0):

An integrated pull up is connected to the digital input.

So, there is always a defined logic state, even if the digital input is not connected.

An open input corresponds to a potential of  $U \ge 3.5V$  and the logical state "inactive".

By applying a voltage U ≤ 1,5V, the digital input can be switched to the logical state "active".

Value / Function I/O	Connection		Logic state	
		Din1	Din2	Din3
	U ≥ 3.5 V	active	active	active
0 (digital input high active)	U ≤ 1.5 V	inactive	inactive	inactive
, , ,	No connection	inactive	inactive	inactive
	U ≤ 1.5 V	inactive <sup>1)</sup>	inactive <sup>1)</sup>	active
1 (digital input low active)	U ≥ 3.5 V	inactive	inactive	inactive
	No connection	inactive	inactive	inactive
Other <sup>2)</sup>		inactive	inactive	inactive

<sup>1)</sup> Function Digital input low active is not available for I/O 1 and I/O 2

The logic state is always inactive

The logic levels are based on the CMOS 5V technology standard.

<sup>2)</sup> If no digital input is selected for the function, the logic state is always inactive

## Analog input

Analog inputs are used for the functionality of the parameters

- Set value source (see 2.14)
- Sensor actual value source (see 2.41)
- (see 2.46)

If an analog input is selected as source for one of these parameters, the corresponding I/O must be configured as analog input here.

If an I/O is not configured as analog input, Ain1 / Ain2 is always set to the value 0 V or 4 mA irrespective of the signal applied.

Analog input Ain1 can only be configured as voltage input 0-10 V.

Configuration as current input 4-20 mA is not possible. In this case, Ain1 is always set to the value 0 V or 4 mA irrespective of the signal applied.

## Analog output 0-10 V

The parameters Function output 0-10 V (see 2.37.1) and Characteristic curve output 0-10 V (see 2.37.2) define a quantity which can be output as voltage value 0-10 V.

To enable this voltage to be output, I/O 3 has to be configured as analog output 0-10 V.

#### Tach output

With configuration as tach output, a frequency proportional to the speed is output at the I/O (speed monitoring). The number of pulses per revolution is specified by the parameter Function output 0..10 V / speed monitoring (see 2.37.1).

The frequency at the tach output is:

$$f \ tach \ Hz = Pulses \ per \ revolution \cdot \frac{n \ rpm}{60}$$

Speed n .....

Pulses per revolution ...... Parameter Speed monitoring - see 2.37.1

I/O 1 is designed as open collector output. A customer pull-up is required here.

I/O 3 outputs a square-wave signal with levels 0V (low) and 10V (high)

### Diagnostic output

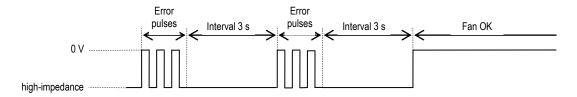

With configuration as diagnostic output, a pulse sequence from which the motor status (see 3.9) can be determined is output at the I/O.

The pulses have a frequency of 2 Hz. An interval of 3 seconds is always inserted after a complete pulse sequence.

Number of pulses	Error
1	Phase failure (3-phase devices) or line undervoltage (single-phase devices)
3	Output stage overheating
4	Communication error between master controller and slave controller
6	Motor overheating
7	Hall sensor error
8	Motor blocked
9	Speed limit exceeded
11	Rotor position sensor calibration error
13	DC-link undervoltage

In the event of several simultaneous errors, the corresponding pulse sequences are output successively. A static level is output if there is no error.

#### Waveform I/O 1:

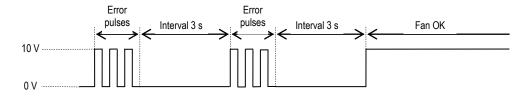

## I/O 1 is designed as open collector output. A customer pull-up is required here.

Recommendation for visual indication by LED:

At I/O 1 the LED is connected via a series resistor to a voltage source.

The LED then lights continuously when "Fan OK". In the event of an error the LED shows the above number of flashing pulses

### Waveform I/O 3:

## I/O 3 outputs a square-wave signal with levels 0V (low) and 10V (high)

Recommendation for visual indication by LED:

At I/O 3 the LED is connected via a series resistor to GND.

The LED then lights continuously when "Fan OK". In the event of an error the LED shows the above number of flashing pulses.

### PWM input

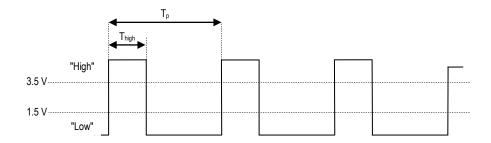

The PWM input is used for the functionality of the parameters

- Set value source (see 2.14)
- Fail-safe set value source (see 2.46)

If a PWM input is selected as source for one of these parameters, I/O 3 must be configured as PWM input

If I/O 3 is not configured as PWM input, the PWM modulation level PWMin3 is always set to the value 0% irrespective of the signal applied.

#### Level:

U ≥ 3.5 V: "High" level U ≤ 1.5 V: "Low" level

The PWM modulation level at I/O 3 (PWMin3) designates the ratio PWMin3 % =

## Open collector signal:

In the configuration "PWM input", I/O 3 has an integrated pull-up. This means that an open collector signal can be connected to this input. The level actively pulled to GND corresponds to a low level, whereas the level not actively pulled to GND corresponds to a high level.

## Frequency:

A frequency range of 40 Hz - 10 kHz is supported.

PWM signals outside this frequency range cannot be evaluated by the fan.

## 2.45.2 Help with settings

Several parameters have to be set to allocate a desired functionality to an I/O. This overview lists all the parameters required to allocate the desired functionality to an I/O.

#### 2.46 Fail-safe set value source

: D15C Address

Write authorization : ebm-papst, customer

## Coding:

This parameter specifies the source through which the fail-safe operation set value is specified.

Value	Fail-safe function set value source
0	Fail-safe function inactive
1	Fail-safe function set value specified by parameter set value for fail-safe
	function (see 2.47)
2	Fail-safe function set value specified by analog input Ain1
3	Fail-safe function set value specified by analog input Ain2
4	Fail-safe function set value specified by PWM input PWMin3

The MSB has no significance. Permissible value range: 0..4

#### **Function:**

The fail-safe function monitors the set value signal wire and reacts in the event of signal failure. The set value signal wire to be monitored is defined by the parameters Set value source (see 2.14) and Switch for set value source (see Fehler! Verweisquelle konnte nicht gefunden werden.).

A break in the signal wire is defined as follows:

#### Signal wire = RS485:

No command is issued to the fan within the time span specified in the parameter "Time lag fail-safe speed" (see 2.48).

#### Signal wire = Analog input Ain1:

The voltage at the analog input Ain1 drops below the value defined in the parameter "Cable break detection voltage" (see 2.50).

#### Signal wire = Analog input Ain2:

The voltage at the analog input Ain2 drops below the value defined in the parameter " Cable break detection voltage " (see 2.50).

#### Signal wire = PWM input PWMin3

The input signal is statically "high" (U ≥ 3.5 V). This corresponds to the signal at an input with no connection. In this case the PWM modulation level is determined as PWMin3 = 100%.

If a break in a signal wire is detected. the fan automatically switches to the selected Fail-safe speed set value source. At the same time the direction of rotation is set to the value "Rotating direction fail-safe mode" (see 2.49).

If the signal wire and the Fail-safe speed set value source are identical (e.g. signal wire = Ain1 and Fail-safe speed set value source = Ain1), the fail-safe function is inactive.

The Fail-safe speed set value signal wire (Fail-safe speed set value source) itself is not additionally monitored for signal failure in fail-safe operation.

## 2.47 Set value for fail safe function

Address : D15D

Write authorization : ebm-papst, customer

If a break is detected in the set value signal wire, the fan automatically switches to the fail-safe mode set value specified here. For further information on the function, see 2.46.

## Coding:

Notes: The coding corresponds to the coding of the set value (D001)

The 4 LSBs have no significance for the set value and are always assumed to be 0.

## a) In closed loopp speed control operating mode

The fail safe function set value designates a speed:

Fail safe set value rpm = 
$$\frac{Data\ bytes}{64000} \cdot nMax\ rpm$$

nMax rpm ... maximum speed in revolutions per minute (see 2.31 Maximum speed)

The value zero means motor standstill

### b) In open-loop PWM control operating mode

The fail safe function set value designates a modulation level:

Fail safe set value 
$$\% = \frac{Data\ bytes}{65536} \cdot 100\%$$

The value zero means motor standstill

### c) In closed loop sensor control operating mode

The fail safe function set value designates a sensor quantity:

A sensor which converts the control variable into a voltage of 0..10 V or 4..20 mA must be connected to the

A set value can be entered for the output voltage or output current of the sensor used.

The fail-safe function set value for the control variable is then obtained from the set value parameter and the characteristic curve Cv(U/I) of the sensor used.

Cv (U) = Control variable as a function of voltage

Fail safe value 
$$V = \frac{Data\ bytes}{65536} \cdot 10V$$

Fail safe set value unit(Rg) = 
$$Cv$$
 (fail save set value V)  
=  $Cv$  ( $\frac{Data\ bytes}{65536} \cdot 10V$ )

or

Cv (I) = Control variable as a function of current

Fail safe set value 
$$mA = \frac{Data\ bytes}{65536} \cdot 16mA + 4mA$$

Fail safe set value unit(Cv) = 
$$Cv$$
 (fail safe set value V)  
=  $Cv$  ( $\frac{Data\ bytes}{65536} \cdot 16mA + 4mA$ )

## 2.48 Time lag fail-safe speed

Address : D15E

Write authorization : ebm-papst, customer

Only for set value specification by RS485:

If no command is issued to the fan for the time specified here, the fan automatically switches to the selected Fail-safe speed set value source. At the same time the direction of rotation is set to the value "Rotating direction fail-safe mode" (see 2.49). For further information on the function, see 2.46.

### Encoding:

Fail – safe time lag ms = Data bytes · 100ms

The MSB is of no relevance!

# 2.49 Rotating direction fail-safe mode

Address : D15B

Write authorization : ebm-papst, customer

If the fail safe function is active and a break in the set value signal wire is detected, the direction of rotation is set to the value defined here. The settings of the parameters Preferred running direction (see 2.17) and Switch for rotating direction source (see 2.16) are not relevant in this case.

For further information, see 2.46

## Coding:

Value	Rotating direction fail-safe mode
0	Counter-clockwise
1	Clockwise
2	None (set direction of rotation is retained)

The MSB has no significance.

Permissible value range: 0..2

## 2.50 Cable break detection voltage

Address : D15F

Write authorization : ebm-papst, customer

Only for set value specification by analog input Ain1 or Ain2

If the voltage at the set value input Ain1 or Ain2 drops below the value defined here, the fan automatically switches to the selected Fail safe speed set value source. At the same time the direction of rotation is set to the value "Rotating direction fail-safe mode" (see 2.49). For further information on the function, see 2.46.

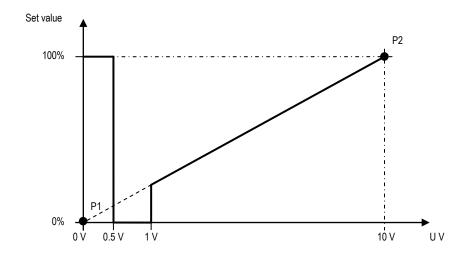

## Encoding:

$$U_{cable\ break\ V} = \frac{Data\ bytes}{65536} \cdot 10V$$

### Example:

Fail-safe mode function = onSet value fail-safe speed = 100%Input characteristic curve U\_open circuit = 0.5 VInput characteristic curve P1 = (0 V | 0%)Input characteristic curve P2 = (10 V | 100%)Motor stop enable = 1

This yields the following characteristic curve:

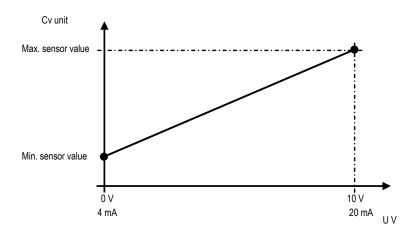

## 2.51 Sensor

Address for min. sensor value : D160 / D161 Address for max. sensor value : D162 / D163 Address of sensor unit : D164 - D169

Write authorization : ebm-papst, customer, end customer

These values define the characteristic curve of the connected sensor as shown in the following graph.

The specifications required for Min. sensor value and Max. sensor value can be found in the sensor data sheet.

These parameters are only intended for processing in the master. Fan action is not influenced by these parameters.

## Coding:

## a) Minimum sensor value

Min. sensor value phys. unit = Data bytes

The minimum sensor value is stored in "IEEE float" format.

## b) Maximum sensor value

Max. sensor value phys. unit = Data bytes

The maximum sensor value is stored in "IEEE float" format.

## c) Sensor unit

Sensor unit ASCII = Data bytes

The sensor unit is stored in "ASCII" format.

## 2.52 Switch for Enable / Disable input source

Address : D16A

Write authorization : ebm-papst, customer, end customer

Coding:

This parameter specifies whether the Enable / Disable function is determined by a digital input or by the internal parameter.

Value	Enable / Disable function by
0	Inactive
1	Parameter "Enable / Disable" (see 2.11 Enable / Disable)
2	Digital input Din1 (Disable input)
3	Digital input Din2 (Disable input)
4	Digital input Din3 (Disable input)
5	Digital input Din1 (Enable input)
6	Digital input Din2 (Enable input)

The MSB has no significance.

Permissible value range: 0..6

Function:

The signal has two states: enabled / disabled

The fan can only be started in "enabled" state.

In "disabled" state the fan is stationary irrespective of any set value specification.

All errors are reset on transition from "enabled" to "disabled" state

This action corresponds to setting of the "Error" bit in the parameter Reset (see 2.2)

The following table provides an overview of the Enable / Disable signal state

Enable / Disable source	0	1	1	2	2	3	3
Enable / Disable RS485	X	0	1	X	X	X	X
Digital input Din1	X	X	Х	active	inactive	Х	Х
Digital input Din2	X	X	Х	X	Х	active	inactive
Digital input Din3	X	X	Х	X	Х	Х	Х
Enable state	Enabled	Disabled	Enabled	Disabled	Enabled	Disabled	Enabled

Enable / Disable source	4	4	5	5	6	6
Enable / Disable RS485	X	Х	Х	Х	Х	Х
Digital input Din1	X	X	active	inactive	X	Χ
Digital input Din2	Χ	X	X	X	active	inactive
Digital input Din3	active	inactive	Х	Х	Х	Х
Enable state	Disabled	Enabled	Enabled	Disabled	Enabled	Disabled

For definition of active / inactive: see 2.45

### 2.53 Stored enable/disable

Address : D16B

Write authorization : ebm-papst, customer, end customer

If the function "Store set value" is active (see 2.18), the value of the parameter "Enable / Disable" (see 2.11) is copied into the parameter "Stored enable/disable" following interruption of the power supply.

Once the power supply has been restored, the value of the parameter "Stored enable/disable" is copied into the parameter "Enable/Disable"

As the parameter Enable/Disable is located in the volatile memory, this value (if applicable) has to be saved in the non-volatile memory as well to permit retention of the existing state following interruption and restoration of the power supply. The parameter "Stored enable/disable" is intended for this purpose.

### Coding:

Value	Enable / Disable
0	Off (no enable)
1	On (enable)

Permissible value range: 0..1

## 2.54 Voltage output

Address : D16E

Write authorization : ebm-papst, customer, end customer

A fixed voltage value between 3.3 and 24 V can be output at the voltage output, e.g. for supplying sensors. The voltage value can be set with this parameter.

## Coding:

$$U\_Output V = \frac{Data \ bytes}{65536} \cdot 20.7 V + 3.3 V$$

## 2.55 RFID access

Address : D16F

Write authorization : ebm-papst, customer

Coding:

LSB 0 0	0	0	0	0	0	RFID
---------	---	---	---	---	---	------

The MSB has no significance.

RFID = 0 : Access to parameter via RFID interface not permitted RFID = 1 : Access to parameter via RFID interface permitted

### 2.56 Customer data

Address : D170 - D17F

Write authorization : ebm-papst, customer

A total of 16 parameters (of 16 bits each) are available to the customer in this area.

Any values can be stored here.

Fan action is not influenced by these parameters.

## 2.57 Operating hours counter (back-up)

Address : D180 Write authorization : ebm-papst

Coding:

Operating time h = Data bytes

This parameter is a back-up copy of the parameter D009 "Operating hours counter" (see 2.7 Operating hours counter). The parameter is constantly updated.

## 2.58 Error history

Error indicator address : D182 1st error address : D184 Time of 1st error address : D185

Error history 1..13 address : D186, D188, D18A, D18C, D18E, D190, D192, D194, D196, D198,

D19A, D19C, D19E

Error history 1..13 time address: D187, D189, D18B, D18D, D18F, D191, D193, D195, D197, D199,

D19B, D19D, D19F

Write authorization : ebm-papst

### A) 1st error

The 1st error occurring in the fan life cycle is stored under the parameter "1st error".

The count of the operating hours counter at this time is also stored in the parameter "1st error time". The parameters are written automatically by the fan.

## B) Error history

The last 13 errors that have occurred in the fan are stored in the error history.

The corresponding count of the operating hours counter is stored for each error in the parameter "Error history time". The parameters are written automatically by the fan.

The error indicator (D182) gives the address of the last error to occur in the error history.

The preceding error is then at the preceding address.

#### Example:

Error indicator = D196

#### Then:

Last error (error n)	D197	Time of last error (error n)
Error n-1	D195	Time of error n-1
Error n-2	D193	Time of error n-2
Error n-3	D191	Time of error n-3
Error n-4	D18F	Time of error n-4
Error n-5	D18D	Time of error n-5
Error n-6	D18B	Time of error n-6
Error n-7	D189	Time of error n-7
Error n-8	D187	Time of error n-8
Error n-9	D19F	Time of error n-9
Error n-10	D19D	Time of error n-10
Error n-11	D19B	Time of error n-11
Error n-12	D199	Time of error n-12
	Error n-1 Error n-2 Error n-3 Error n-4 Error n-5 Error n-6 Error n-7 Error n-8 Error n-9 Error n-10 Error n-11	Error n-1 D195 Error n-2 D193 Error n-3 D191 Error n-4 D18F Error n-5 D18D Error n-6 D18B Error n-7 D189 Error n-8 D187 Error n-9 D19F Error n-10 D19D Error n-11 D19B

Each time a new error occurs, the error indicator is incremented by 2 and both the error and the time are stored at the address shown by the error indicator. The addresses are written automatically by the fan in this process.

When the error indicator reaches the last value D19E, it will be reset to the first value D186 when the next error occurs.

#### Coding:

## Error indicator:

Address of error indicator = Data bytes

#### Error:

MSB	0	0	0	0 *)	0	0	0	n_Limit
LSB	BLK	HLL	TFM	0 *)	SKF	TFE	0	0 *)

If bit = 1, the error described below has occurred:

n\_Limit: Speed limit exceeded

BLK: Motor blocked HLL: Hall sensor error TFM: Motor overheating

SKF: Communication error between bus controller and commutation controller

TFE: Output stage overheating

#### Note:

The errors "Communication error" and "Speed limit exceeded " are only stored if the last error was a different one, as restarting is permitted with this error.

#### Error time:

 $Time\ of\ error\ h\ =\ Data\ bytes$ 

<sup>\*)</sup> The errors "DC-link undervoltage", "Rotor position sensor calibration error" and "Phase failure" and the general error identifier "Fan Bad" are not stored even if they are set in the motor status (see Motor status).

## 2.59 DC-link voltage reference value

Address : D1A0 Write authorization : ebm-papst

All values for the DC-link voltage are based on this reference value to keep the resolution variable.

Coding:

 $Reference\ Uz\ mV = Data\ bytes \cdot 20\ mV$ 

## 2.60 DC-link current reference value

Address : D1A1

Write authorization : ebm-papst

All values for the DC-link current are based on this reference value to keep the resolution variable.

Coding:

 $Reference\ Iz\ mA = Data\ bytes \cdot 2\ mA$ 

## 2.61 Production data

The manufacturing data contain information to be able to identify the device concerned. Fan action is not influenced by these parameters.

#### 2.61.1 Fan serial number and date of manufacture

Serial number address : D1A2 / D1A3
Date of manufacture address : D1A4
Write authorization : ebm-papst

ebm-papst allocates an individual serial number for each fan. The part which customers can read out is made up of the date of manufacture and the consecutive number. Addressing is also possible with this. Should any unexpected problems arise, please inform us accordingly.

Format: YYWW00XXXX

YY : Year of manufacture WW : Week of manufacture 00 : Fixed value 00

00 : Fixed value 00 XXXX : Consecutive number

The first 4 characters contain the date of manufacture (year / week).

The number XXXX starts running at zero at the start of each week of manufacture and is incremented by 1 for each fan. Each character can assume values from 0-9 and from A-Z. This yields a maximum encodable number of 36 characters per position, i.e.  $36^4 = 1679616$  devices / week

## a) Serial number (D1A2 / D1A3)

Only the XXXX part (consecutive number) is stored in the parameter "Serial number". Each character is encoded as an ASCII value.

#### Codina:

Serial number ASCII = Data bytes

## b) Date of manufacture (D1A4)

The YYWW part is stored in the parameter "Date of manufacture". Each character is encoded as a hex value.

## Coding:

Production year = Data bytes (MSB) Production week = Data bytes (LSB)

## Example:

ebm-papst serial number: 09230012GY

-> Content D1A2: 0x4759 (GY) Content D1A3: 0x3132 (12) Content D1A4: 0x0917 (09/23)

## 2.61.2 Fan type

Address : D1A5 - D1AA Write authorization : ebm-papst

### Coding:

The fan type is stored here in ASCII characters D1A5 contains the first two characters of this. D1AA contains the last two characters.

## 2.62 Rotor position sensor

## 2.62.1 Rotor position sensor calibration

Address : D1F8 Write authorization : ebm-papst

Coding:

MSB	0	0	0	0	0	0	0	0
LSB	0	0	0	0	0	0	0	Cal

Cal ...... Trigger rotor position sensor calibration process

## Calibration procedure:

When Cal = 1 a rotor position sensor calibration process is triggered.

This calibration process is displayed

In the input register Warning bit 8 RL\_Cal (see 3.10)

The following parameters are automatically set to defined values at the start of the calibration process:

The settings of the corresponding parameters are ignored during the calibration process

- Control limitation = 0 (all limitations are inactive) see 2.36
- Operating mode = 2 (open-loop PWM control) see 2.21
- Set value = Rotor position sensor calibration set value (see 2.62.2)

Set value specifications from other sources are ignored during the calibration process.

When the calibration process is active, the fan may start up unexpectedly even if the set value specified by the selected set value source is 0.

During the calibration process, make sure the motor is always enabled via a defined Enable / Disable signal if applicable (see 2.52). Otherwise the calibration process cannot be successfully implemented.

If the calibration process was successful

- The request in the holding register Rotor position sensor calibration (bit 0, Cal) is reset
- The display in the input register Warning bit 8 RL\_Cal is reset

The altered settings of the parameters (Control limitation, Operating mode, Set value, see above) are reset to their previous values.

If the calibration process was unsuccessful, an error message is set in the input register Motor status bit 10, RL\_Cal (see 3.9).

The request in the holding register Rotor position sensor calibration (bit 0, Cal) is retained.

Another calibration process cannot be started until the error message has been reset (power supply off / on or via holding register Reset, see 2.2 or via Enable / Disable signal).

As long as the rotor position sensor has not been successfully calibrated, the fan can only be operated in calibration mode. In this case an error message is always generated outside calibration mode.

## 2.62.2 Rotor position sensor calibration set value

Address : D1F7 Write authorization : ebm-papst

During the calibration process the operating mode is automatically set to "Open-loop PWM control". The set value thus always designates a modulation level:

Setvalue calibration 
$$\% = \frac{Databytes}{65536} \cdot 100\%$$

A value of zero means motor still stand.

## 2.63 Mirror function for holding registers

The mirror function for holding registers can be used to select up to 32 holding registers from all the fan holding registers and arrange these in an individual order in a contiguous address area. These individually compiled holding registers can then be addressed with a single read or write command. The transmission speed for all the information required for an application can be optimized using this function.

The mirror function is made up of two register ranges:

- Original addresses of mirrored holding registers (D480 D49F) see 2.63.2
- Mirrored holding registers (D380 D39F) see 2.63.1

A holding register from one of these ranges is always assigned to one from the other range:

Original address of mirrored holding registers	Mirrored holding registers
D480	D380
D481	D381
D482	D382
D483	D383
D484	D384
D485	D385
D486	D386
D487	D387
D488	D388
D489	D389
D48A	D38A
D48B	D38B
D48C	D38C
D48D	D38D
D48E	D38E
D48F	D38F
D490	D390
D491	D391
D492	D392
D493	D393
D494	D394
D495	D395
D496	D396
D497	D397
D498	D398
D499	D399
D49A	D39A
D49B	D39B
D49C	D39C
D49D	D39D
D49E	D39E
D49F	D39F

The addresses of the holding registers which are mirrored are specified in the original address (D480 - D49F). The holding registers which are defined in the corresponding original address can be accessed via the mirrored holding registers (D380 - D39F).

Write access to a holding register of the mirror range (D380 - D39F) also changes the corresponding holding register of the original range (D000 - D37F).

Write access to a holding register of the original range (D000 - D37F) also changes the corresponding holding register of the mirror range (D380 - D39F).

### **Example:**

Holding register address Content

D480 D001 (setpoint)

D481 D106 (operating mode Parameter set 1)

D482 D000 (reset)

D483 D009 (operating hours counter)

With read access to the holding register D380, the set value is obtained.

With write access to the holding register D380, the set value is set.

At the same time the content of the holding register D001 (set value) is set to the same value

With read access to the holding register D381, the operating mode (parameter set 1) is obtained With write access to the holding register D381, the operating mode (parameter set 1) is set At the same time the content of the holding register D106 (operating mode (parameter set 1)) is set to the same value

The same applies accordingly to the following holding registers.

With joint read access to the holding registers D380 - D383, the content of the holding registers Set value, Operating mode (parameter set 1), Reset and Operating hours counter is obtained with a single command.

Joint write access to the holding registers D380 - D383 makes it possible to write the content of the holding registers Setpoint, Operating mode (parameter set 1), Reset and Operating hours counter with a single command.

## 2.63.1 Mirrored holding registers

Address : D380 - D39F

Write authorization : see Original registers

Coding : see Original registers

The content of the holding registers defined in D480 - D49F is mirrored here See above for further information on the function.

## 2.63.2 Original addresses of mirrored holding registers

Address : D480 - D49F

Write authorization : ebm-papst, customer

Coding:

Original address = Data bytes

The addresses of the holding registers which are mirrored in the range D380 - D39F are defined here. See above for further information on the function.

## 2.64 Mirror function for input registers

The mirror function for input registers can be used to select up to 16 input registers from all the fan input registers and arrange these in an individual order in a contiguous address area. These individually compiled input registers can then be addressed with a single read command. The transmission speed for all the information required for an application can be optimized using this function.

The mirror function is made up of two register ranges:

- Original addresses of mirrored input registers (holding registers D400 D40F) see 2.64.1
- Mirrored input registers (input registers D100 D10F) see 3.26

One holding register and one input register from each of these ranges are assigned to one another:

Original address of mirrored input registers (holding registers)	Mirrored input registers (input registers)
D400	D100
D401	D101
D402	D102
D403	D103
D404	D104
D405	D105
D406	D106
D407	D107
D408	D108
D409	D109
D40A	D10A
D40B	D10B
D40C	D10C
D40D	D10D
D40E	D10E
D40F	D10F

The addresses of the input registers which are mirrored are specified in the original address (D400 - D40F). The input registers which are defined in the corresponding original address can be accessed via the mirrored input registers (D100 - D10F).

## **Example:**

Holding register address Content

D400 D011 (motor status)
D401 D010 (actual speed)

D402 D019 (current modulation level)

D403 D021 (current power)

With read access to the input register D100, the motor status is obtained. With read access to the input register D101, the actual speed is obtained. The same applies accordingly to the following input registers.

With joint read access to the input registers D100 - D103, the content of the input registers Motor status, Actual speed, Current modulation level and Current power is obtained with a single command.

## 2.64.1 Original addresses of mirrored input registers

Address : D400 - D40F

Write authorization : ebm-papst, customer

Coding:

Original address = Data bytes

The addresses of the input registers which are mirrored in the input register range D100 - D10F (see 3.26) are defined here. See above for further information on the function.

# **Input registers**

#### 3.1 Overview

The input registers are stored in the RAM of the fan.

The input registers have read access only.

The following list provides an overview of all parameters.

The function of the parameters is described in the following sections

MODBUS	Designation
address	Designation
D000	Identification
D001	Maximum number of bytes
D002	Bus controller software name
D003	Bus controller software version
D004	Commutation controller software name
D005	Commutation controller software version
D010	Actual speed
D011	Motor status
D012	Warning
D013	DC-link voltage
D014	DC-link current
D015	Module temperature
D016	Motor temperature
D017	Electronics temperature
D018	Current direction of rotation
D019	Current modulation level
D01A	Current set value
D01B	Sensor actual value
D01C	Enable / Disable input state
D01D	Current parameter set
D01E	Current controller function
D01F	Reserved
D020	Vacant
D021	Current power
D022	Reserved
D023	Sensor actual value 1
D024	Sensor actual value 2
D025 -	Reserved
D026	
D027	Current power W
D028	Current set value source
D029 -	Energy consumption counter
D02A	
D02B	Reserved
D02C	Reserved
D02D -	Vacant
D0F5	
D0F6 -	Reserved
D0FF	
D100 -	Mirrored input registers

MODBUS address	Designation
D10F	
D110 - D1FF	Vacant
D200 - D2FE	Reserved

## 3.2 Identification

Address : D000

The identification specifies the type of electronics/protocol concerned.

Coding:

Value	Device	Specification Version
00 01	ebm-papst product range 84 / 112 / 150	1.02 *)
00 02	ebm-papst product range 84 / 112 / 150	2.01, 3.00 - 3.01 *)
00 03	Customer application	(*)
00 04	Customer application	*)
00 05	Customer application	*)
00 06	ebm-papst product range 84 / 112 / 150	3.02 *)
00 07	ebm-papst product range 84 / 112 / 150	4.00 *)
80 00	ebm-papst product range 84 / 112 / 150 / 200	5.00 *)
00 09	Customer application	*)
00 0A	ebm-papst product range 84 / 112 / 150 / 200 Lite	5.00 *)
00 0B	ebm-papst product range 84 / 112 / 150 / 200 Lite + plug-in module	5.00 *)
00 0C	Special applications for ebm-papst product range 84/ 112/ 150/ 200	5.02 *)
00 0D	ebm-papst product range 84 / 112 / 150 / 200 Lite	5.01 *)
00 0E	ebm-papst product range	6.00

<sup>\*)</sup> Devices with identification ≠ 0x000E do not correspond to this specification. In such cases use is to be made of the applicable document.

## 3.3 Maximum number of bytes

Address : D001

This parameter specifies the maximum number of bytes which can be contained in a telegram via MODBUS.

Coding:

Max. number of bytes = Data bytes

### Software name of bus controller software name

: D002 Address

This parameter specifies the bus controller software number (without version).

Encoding:

Software name = Data bytes

#### 3.5 Bus controller software version

Address : D003

This parameter specifies the bus controller software version.

Coding:

Software version = Data bytes LSB

The MSB is always 0.

#### 3.6 Commutation controller software name

Address : D004

This parameter specifies the commutation controller software number (without version).

Encoding:

Software name = Data bytes

#### 3.7 **Commutation controller software version**

Address : D005

This parameter specifies the commutation controller software version.

Coding:

Software version = Data bytes LSB

The MSB is always 0.

## 3.8 Actual speed

Address : D010

Coding:

The actual speed is obtained from the speed parameter and the maximum speed:

Actual speed rpm = 
$$\frac{Data\ bytes}{64000} \cdot nMax\ rpm$$

nMax [rpm] ... maximum speed (in revolutions per minute) - see 2.31 Maximum speed

Note:

If the actual speed exceeds the value "1.02 \* Maximum speed", the display is limited to the value "1.02 \* Maximum speed" (0xFFF0)

#### 3.9 Motor status

Address : D011

The motor status indicates current fan errors.

Coding:

MSB	0	0	0	UzLow	0	RL_Cal	0	n_Limit
LSB	BLK	HLL	TFM	FB	SKF	TFE	0	PHA

If a bit is set, the error described below has occurred:

UzLow: DC-link undervoltage

RL\_Cal: Rotor position sensor calibration error (see also 2.62.1)

n\_Limit: Speed limit exceeded

BLK: Motor blocked HLL: Hall sensor error TFM: Motor overheating

FB: Fan Bad (general error) \*)

SKF: Communication error between master controller and slave controller

TFE: Output stage overheating

PHA: Phase failure (3-phase devices) or line undervoltage (single-phase devices)

<sup>\*) &</sup>quot;Fan Bad" is set for every error

## 3.10 Warning

Address : D012

A warning is a precursor to the error message, i.e. the limit value for the error message has almost been reached.

## Coding:

The setting of a bit activates the warning:

MSB	LRF	UeHigh	0	UzHigh	0	Op.circ.	n_Low	RL_Cal
LSB	Brake	UzLow	TEI_high	TM_high	TE_high	P_Limit	L_high	I_Limit

LRF : Shedding function active - (see 2.43 Shedding function)

**UeHigh** : Line voltage high : DC-link voltage high UzHigh

Cable break: cable break at analog input or PWM input for the analogue set valueinput

(voltage at analog input < value for cable break voltage- see 2.50

or signal at PWM input statically high)

n\_Low : Actual speed is lower than run monitoring speed limit

(see 2.40 Run monitoring speed limit).

RL\_Cal : Calibration of rotor position sensor in progress (see 2.62.1)

**Brake** : Braking mode: set in the case of external drive in opposite direction

at high speed for lengthy period

UzLow : DC-link voltage low

TEI\_high : Temperature inside electronics high

TM\_high : Motor temperature high TE high : Output stage temperature high

: Power limiter in action P\_Limit

: Line impedance too high (DC-link voltage unstable) L high

I Limit : Current limitation in action

# 3.11 DC-link voltage

Address : D013

Encoding:

$$Uz V = \frac{Data \ byte}{256} \cdot Reference \ Uz V$$

Reference Uz .......DC-link voltage reference (see 2.59 DC-link voltage)

## 3.12 DC-link current

Address : D014

Coding:

$$Iz A = \frac{Data \, bytes}{256} \cdot Reference \, Iz \, A$$

Reference Iz .......... DC-link current reference (see 2.60 DC-link current reference value)

## 3.13 Module temperature

Address : D015

Coding:

 $T \_Modul \circ C = Data bytes$ 

Format: signed integer

# 3.14 Motor temperature

Address : D016

Coding:

 $T \_Motor \circ C = Data bytes$ 

Format: signed integer

# 3.15 Electronics temperature

Address : D017

Coding:

 $T_EI^{\circ}C = Data bytes$ 

Format: signed integer

## 3.16 Current direction of rotation

: D018 Address

Coding:

Value	Current direction of rotation
0	Counter-clockwise
1	Clockwise

## 3.17 Current modulation level

Address : D019

Coding:

 $Modulation \ level = \frac{Data \ bytes}{65536} \cdot 100\%$ 

## 3.18 Current set value

Address : D01A

Coding:

a) In closed loop speed control operating mode

The set value designates a speed:

Set value rpm =  $\frac{Data\ bytes}{64000} \cdot nMax\ rpm$ 

nMax rpm ... maximum speed in revolutions per minute (see 2.31 Maximum speed)

The value zero means motor standstill

b) In open-loop PWM control operating mode

The set value designates a modulation level:

Set value  $\% = \frac{Data\ bytes}{65536} \cdot 100\%$ 

The value zero signifies motor standstill

### c) In closed loop sensor control operating mode

The set value denotes a sensor quantity:

A sensor which converts the control variable into a voltage of 0..10 V or 4..20 mA must be connected to the

A set value can be entered for the output voltage or output current of the sensor used. The set value for the control variable is then obtained from the set value parameter and the characteristic curve Cv (U/I) of the sensor used.

Cv (U) = Control variable as a function of voltage

$$Set \ value \ V \quad = \quad \frac{Data \ bytes}{65536} \cdot 10 \ V$$

Set value unit(Cv) = 
$$Cv$$
 (Set value V)  
=  $Cv$  ( $\frac{Data\ bytes}{65536} \cdot 10V$ )

or

Cv (I) = Control variable as a function of current

Set value 
$$mA = \frac{Data\ bytes}{65536} \cdot 16mA + 4mA$$

Set value unit(Rg) = 
$$Cv$$
 (Set value V)  
=  $Cv$  ( $\frac{Data\ bytes}{65536} \cdot 16mA + 4mA$ )

#### 3.19 Sensor actual values

Sensor actual value address : D01B Sensor actual value 1 address : D023 Sensor actual value 2 address : D024

2 sensors can be connected to the fan.

The sensor actual value 1 outputs the current actual value of the external sensor at the analog input Ain1. The sensor actual value 2 outputs the current actual value of the external sensor at the analog input Ain2.

The sensor actual value (D01B) valid for the controller is determined from these two values on the basis of the sensor actual value source (see 2.41 Sensor actual value source). Only this actual value is used in "Closed loop sensor control" operating mode.

## Encoding:

$$Actual \ value \ V = \frac{Data \ byte}{65536} \cdot 10V$$

Actual value unit(Rg) = Rg (U)  
= Rg (
$$\frac{Data\ byte}{65536} \cdot 10V$$
)

## Encoding:

$$Actual \ value \ V = \frac{Data \ byte}{65536} \cdot 10 \ V$$

Actual value unit(Cv) = 
$$Cv(U)$$
  
=  $Cv(\frac{Data\ byte}{65536} \cdot 10V)$ 

Actual value V = Sensor output voltage Cv (U) = Sensor characteristic curve as a function of voltage

or

Actual value 
$$mA = \frac{Data\ byte}{65536} \cdot 16mA + 4mA$$

Actual value unit(
$$Cv$$
) =  $Cv(I)$   
=  $Cv(\frac{Data\ byte}{65536} \cdot 16mA + 4mA)$ 

Actual value mA = Sensor output current Cv (I) = Sensor characteristic curve as a function of current

## 3.20 Enable / Disable input state

Address : D01C

This parameter indicates the state of the Enable / Disable input.

The state of the Enable / Disable input depends on the holding registers Switch for Enable / Disable source (see 2.52) and Enable / Disable (see 2.11) as well as the digital inputs Din1, Din2 and Din3. For logic table for selection, see 2.52

### Coding:

Value	Enable / Disable
0	Enable off (motor stop)
1	Enable on (motor start permitted)

## 3.21 Current parameter set

Address : D01D

This parameter indicates which parameter set (1 or 2) is currently being used.

The parameter set depends on the holding registers Switch for parameter set source (see 2.19) and Parameter set internal (see 2.20) as well as the digital inputs Din1, Din2 and Din3. For logic table for selection, see 2.19

#### Coding:

Value	Parameter set
0	Parameter set 1
1	Parameter set 2

### 3.22 Current controller function

Address : D01E

This parameter indicates which controller function is currently being used.

The controller function depends on the holding registers Source for controller function (see 2.22) and Controller function (see 2.23) as well as the digital inputs Din1, Din2 and Din3. For logic table for selection, see 2.22.

#### Coding:

	Value	Controller function
	0	Positive: Control variable = set value - actual value
	1	Negative: Control variable = actual value - set value

### Notes:

For closed-loop sensor control with a temperature sensor a positive controller function is synonymous with "Heating" and a negative controller function is synonymous with "Cooling".

## 3.23 Current power

## 3.23.1 Relative coding

Address : D021

Encoding:

$$PW = \frac{Data\ bytes}{65536} \cdot References\ Uz\ V \cdot References\ Iz\ A$$

Reference Uz ......DC-link voltage reference value (see 2.59 DC-link voltage reference value) Reference Iz ............ DC-link current reference value (see 2.60 DC-link current reference value)

### 3.23.2 Absolute coding W

Address : D027

Coding:

PW = Data bytes

The numerical value of the input register corresponds directly to the current power in W Further calculation using the reference values for DC-link voltage and DC-link current is not necessary.

## 3.24 Current set value source

Address : D028

This parameter indicates which set value source is currently being used.

The set value source depends on the holding registers Switch for set value source (see Fehler! Verweisquelle konnte nicht gefunden werden.) and Set value source (see 2.14) as well as the digital inputs Din1, Din2 and Din3.

For logic table for selection, see Fehler! Verweisquelle konnte nicht gefunden werden..

The set value source can also be influenced by the emergency operation function (see 2.46).

## Coding:

Value	Set value source
0	Analog input Ain1
1	RS485 (parameter Set value D001)
2	Analog input Ain2
3	PWM input PWMin3
255	Set value for fail-safe function (see 2.47)

## 3.25 Energy consumption counter

Address : D029 (MSB) / D02A (LSB)

Coding:

Energy consumption kWh = Data bytes

These input registers indicate the energy consumption of the fan since its delivery.

## 3.26 Mirrored input registers

Address : D100 - D10F

Coding : see Original registers

The content of the input registers defined in the holding registers D400 - D40F is mirrored here. For further information on the function, see 2.64 Mirror function for input registers.
